And in accordance with law, and an order of the Board of Directors, made on the 14th day of January, 1875, so many shares of each parcel of said stock as may be necessary, will be sold at public auction at the office of the Company, room 16, 408 California street, San Francisco, Cal., on the 5th day of March, 1875, at the hour of 12 o'clock, m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

J. W. TRIPP, Secretary.

Office, room 16, 408 California street, San Francisco, California.

Confidence Mining Company—Location

of principal place of business, San Francisco, California. Location of works, Tuolumne County, State of California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the sixteenth day of January, 1875, an assessment of thirty (30) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, 210 Battery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 24th day of March, 1875, will be delinquent, and unless payment is made before, will be sold on Wednesday, the seventeenth day of March, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. S. ANDERSON, Secretary.

Office, 210 Battery street, San Francisco, Cal.

Electric Mining Company—Principal

place of business, San Francisco, State of California. Location of works, Lincoln Mining District, Butte County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 16th day of February, 1875, an assessment of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the Company, in San Francisco.

Any stock upon which this assessment shall remain unpaid on the 24th day of March, 1875, will be delinquent, and unless payment is made before, will be sold on Monday, the 12th day of April, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

T. B. WINGARD, Secretary.

Office—Room 13, No. 318 California street, San Francisco

Geneva Consolidated Silver Mining Com-

pany. Principal place of business, City and County of San Francisco, State of California. Location of works, Cherry Creek Mining District, White Pine County, Nevada.
Notice is hereby given that at a meeting of the Board of Directors, held on the 24 day of January, 1875, an assess-

ment of twenty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 14, 302 Montgomery street, San Francisco.
Any stock upon which this assessment shall remain unpaid on the 8th day of February, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday the first day of March, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office—Room 14, No. 302 Montgomery street, S. F.

POSTPONEMENT.—The time when the above assessment will become delinquent is postponed to the eighth (8th) day of March, and the sale of stock for delinquency is postponed to Wednesday, the thirty-first (31st) day of March, 1875, at the same hour and place above mentioned. By order of the Directors.
T. T. MILLIKEN, Secretary.

PURCHASERS please say advertised in Scientific Press

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1874.
JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
2d. The best Concentrator I have ever known—(the concentrated stuff only containing 6 per cent. of sand).
3d. They are good amalgamators, light (feather) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
4th. They require but little power and attention to run them, and with ordinary care will last for years.
I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empires Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,

JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. Co., AMADOR, AMADOR COUNTY.

MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$3,500 per month more than with the blankets and boulders formerly in use.
O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—Dear Sir: Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurates, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.

As further evidences of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection.

E. R. BURKE, Superintendent.

For description send for Circular.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.
It is unequalled for cleansing Woolen Fabrics, Outlets, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing. It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a wash tub of water. For bathing, use one table-spoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterwards. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION, for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

Manufactured by the

Descriptive Circular
SEND FOR

COOK, RYMES & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of OUR MOST SUCCESSFUL MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Reicher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. For sale only at

Steam Pumps

AND

Hot or Cold

Water Pumps

OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. ENGINEERS, TRY IT. For sale in any quantity by **TREADWELL & CO., San Francisco.**

IMPORTANT TO LUMBERMEN.

\$100.00 IN GOLD.

And FIRST PRIZE SILVER MEDAL were awarded to us for the best

SAWS

In the great National contest held at Cincinnati, September, 1874, and lasting over six days. Our celebrated DAMASCOUS TEMPERED SAWS were declared the victors.

We have made special shipping arrangements for very low freights and quick dispatch of our saws for the Pacific Coast. ONLY SEVEN DAYS BY MAIL FROM SAN FRANCISCO. Send your address for a full report of the great National Sawing Contest, and the class of saws that you use, with the thickness, size and kind that you use, and specify such as you will require within the next 60 days. We will guarantee to furnish you with saws that have no equal in quality, and at prices that will be entirely satisfactory. Address

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

Cazin's Combination Ore-Sizer and Con-
centrator—One Plunger System.

(Covered by Letters Patent of July 2d, 1872, and recent
applications.)

Containing a sizing apparatus, (revolving screws) de-
livering two or four sizes of ore to two or four rows of
sieves, each row independent of the other, and each
having 5 sieves, each row concentrating according to
specific gravity the special size automatically fed into
it, resulting in the simultaneous continual delivery of
separated materials, working 2d and 3d-class ores into
1st-class ores of perfect cleanliness. It thoroughly sepa-
rates native gold or copper from quartz or any other
lode matter—galena and silver sulphurets from
pyrites, barytes and quartz; and pyrites from quartz.

Added to a battery of stamps these machines consti-
tute a full system of ore concentration, sufficient in
most cases for the requirements of western mines, with
a capacity of 16 or 20 tons per 24 hours.

VOLUME XXX
Number 9.

A New Fruit Dryer.

The business of fruit drying in this State has, within the past few years, grown to large proportions, and bids fair to be even larger. We now raise much more fruit than home consumption demands, and the consequence of this is that in order to insure the sale of crops the farmers and fruit raisers must dry or otherwise preserve the surplus production. Since it was first demonstrated in California that fruit can be dried with profit a number of fruit dryers have been introduced in the market and several different machines are now in use. We have described all the processes in use here in this paper and now illustrate and describe a new aspirant for public favor.

The dryer illustrated by the accompanying engraving was invented by William S. Plummer, of this city, and has been tested practically for over three months, principally on pumpkins. The process is continuous the fruit being placed on racks which are made to revolve and carry the fruit around a horizontal course through heated chambers and back to the place of starting.

By referring to the cut the general plan of the dryer can be seen. B represents a circular drying chamber in which the racks, A, for holding the fruit are carried. This chamber is enclosed by a stationary circular wall which is provided with a door, to get at the racks, as shown. A steam coil passes all around the interior of the drying chamber on the floor. The heated air from the furnace passes into an air chamber about the foot in height and comes through the perforated floor so that the hot air comes up through the steam coils and is distributed throughout the fruit drying chamber. A steam coil attached to the sliding door, C, is used for giving a greater degree of heat to the fruit as it is first put in.

It will be seen that there are several rows of pipes in this movable coil so arranged that a row of steam pipes passes between each two racks of fruit. A small movable partition is inserted between the row of racks, A, which is to be taken out, and the racks holding the green fruit on the left. By this means when the racks holding the green fruit are put in their place, the chamber is revolved sufficiently to place that section in the position where the sliding coil can be run in between the racks; at the same time the door can be opened and the fruit which has been dried can be removed. The movable coil, C, is so subject the green fruit for short time to a greater heat than can be maintained in the drying chamber, for "bursting the air cells." The slide on which this coil is placed, is to draw the coil and the partition back, momentarily to allow the racks to be run as often as each set is filled with green fruit.

A boiler in another part of the building furnishes steam for the steam coil and for the engine for driving the air pump. An air heater is placed in the furnace under the boiler so that the same fire furnishes both steam and hot air to the fruit dryer. Both boiler and air heating apparatus are placed in a room under the dryer. The fan drives the hot air through the drying chamber and through the escape pipe, D. The revolving chamber in which the fruit is dried, is suspended on a frame by means of an axle, so that it may revolve around the central support, E. The steam coils are laid on the floor and the hot air enters through the stationary side of the chamber at a point behind the movable coil, C. The hot air thus comes completely around the chamber before it escapes at D. By this means both hot air and steam are used in drying the fruit and as one batch of fruit is dried and removed another batch is put in the chamber. The machine which we examined at Spaulding & Bros., 31 Beale street, is 24 feet in diameter and has room for 140 trays. The trays have a superficial area of about one square foot. Six trays are put in about every twelve minutes. Mr. Plummer states that he easily dries 500 trays in a day, for as fast as one batch is finished another is put in. The capacity of

the machine is only limited by the size of the chamber. The same fire heats the air and furnishes the steam for steam coils and engine. This dryer can be attached to any steam engine and boiler now in use at a saving of from \$500 to \$1,000 on the first cost.

The arrangement of this dryer is quite simple, and it seems to be effective. While we were examining the machine one day this week they were drying pumpkins, and those removed from the machine were immediately ground to a fine powder. The amount of pumpkin dust in the room showed plainly that the pumpkins had been thoroughly dried. This finely powdered pumpkin is put up in small packages and sold.

These fruit dryers are sold at a comparatively low price. No. 1, which is 22 feet in diameter,

The City of Peking.

That noble specimen of naval architecture, the "City of Peking," sailed from this city on Saturday last. Invitations were issued by the agent of the P. M. S. S. Co. in this city to a number of persons, to take a short excursion around the bay in the "Peking" before her departure. The guests were transferred to the steamer "Arizona" when near Hunter's Point, and both vessels sailed in company as far as Fort Point, where farewells were exchanged, and the "City of Peking" passed on through the Golden Gate on her voyage to China. A number of small steamers and tug-boats accompanied the large steamer to the Gate, and then whistles and bells, with the band, and the boom-

ship ten or twelve knots an hour. There was no jurr or trembling whatever caused by the propeller. The vessel was stopped and started several times and it was impossible to tell by any jarring whether the propeller was revolving or not. The quietness with which the machinery worked was marvelous. It went like clockwork, and with not much more noise. After getting aboard the "Arizona" and steaming alongside the "City of Peking" one could realize better the proportion of the latter. She cut the water smoothly and took the water for about 30 or 40 feet without a ripple. At a point that distance from the entrance a slight curly wave rolled over, but from the aft there was not a ripple. She was drawing 24 feet of water, and her wake was as clean and smooth as that of a captain's gig, no foam or signs of agitation in the water being perceptible. After leaving Alcatraz they "opened her out" and she showed a clean pair of heels to the "Arizona," the "Antelope," the "General McPherson," and the new tug "Reeue," which steamers were escorting her out. As a specimen of naval architecture and ingenious mechanism the "City of Peking" and her engines are a credit to America.

Reworking Old Ground.

The effect of the United States law requiring expenditure on mining claims annually has caused the relocation of many old, abandoned claims throughout the country. From all parts of this and neighboring States we hear of old claims being reworked, and many of them with good results. The abandonment of a mining claim does not always indicate worthlessness by any means, for in many cases it is caused by want of capital or a desire to seek new fields. Moreover, the causes which made many miners abandon their claims in some localities have been removed. New mills have been built in districts where formerly there were none; railroads have brought other mining camps into notice; new methods of working refractory ores have been devised, and capital has come to the assistance of labor.

We hear of new mines coming to the front every day, many of them in old districts, and the prospector has work before him for many a year to come. Still, there are numbers of mines which were originally located years ago, which from adverse circumstances were not worked, but which are as good now as some of the new mines. In some of the old districts "revivals" have taken place, and work recommenced with vigor. As an instance of this we can mention the celebrated Meadow Lake district, several developments in which, the Truckee Republican says, give promise of a revival of the abandoned city, more than thirty claims having been relocated. It is also reported that persons in the lower part of the county contemplate running a stage line from Cisco to Meadow Lake. This place has been considered quite a romantic spot on account of its being utterly deserted, and several pretty little stories have been written about it. Now, however, it seems that the spirit of progress has reached it again, and the grass-grown streets will once more know the foot of man.

Another instance which can be mentioned is Forbestown, formerly a famous mining town, which the Oroville Mercury says has all at once taken a new lease of life and is going ahead at a rapid rate. New buildings are going up, and new faces are to be seen every day on the street, seeking their homes. The work carried on by the mill company is giving employment to many, and the prospect is good that as soon as the new company get in running order there will be employment for a great many new hands, especially quartz miners. The placer mines are by no means exhausted yet, and many find employment in them.

It is not, however, in totally abandoned camps that the work of relocation is most marked, but in camps where great rushes have been made for fortunes, and where they were not made in a day they were left for other places. Miners recognize now, more forcibly than ever, that they, like most other men, must be content with modest profits, although, at the same time, they stand a chance of something handsome. We are glad to note the fact that so many old claims have been taken up again and worked, knowing that it augurs renewed prosperity in mining matters.

PLUMMER'S PATENT FRUIT DRYER.

is sold for \$2,500; No. 2, which is 24 feet in diameter is \$3,000, and No. 4 is sold for \$4,000 and is 28 feet in diameter. No. 3 has 24 sections and holds 168 trays. There are seven trays to each section in all the different sizes. These prices include the whole machine, engine, boiler, pump, steam coils, patent right and all; parties buying only furnishing their own building. The engine furnished is five horse power, and may be used for other purposes, such as pumping, etc. Mr. Plummer is confident that he can introduce his dryer all over the State, as its construction is so simple that he can sell it cheap. As will be seen from what we have said its capacity is great, and the operation of drying is continuous. As fast as one tray is put in another is removed, by simply turning the revolving chamber one section, the catch E, regulating it so that the trays always come exactly in front of the doors. The machine is easily revolved by a light crank, the position of which is close behind the escape pipe, D. The arrangement of the movable coils, C, is particularly ingenious, as considerable heat is concentrated exactly where it is wanted, and at the time it is wanted, namely, when the fruit is first put in the dryer. The machine does not take up much room and may be erected in a shed. The walls of the revolving chamber are lined with felt to prevent the escape of heat. The hot air is compelled to pass through all the fruit in the dryer before it can escape, and the steam coils extend around the whole machine. It will be observed that this fruit dryer differs from others now in use in several particulars, and it is the only one in which a horizontal revolving motion is accomplished. Those desiring further information concerning it can send for circulars to Spaulding Bros, 31 Beale street, in this city.

ing of the big guns from Alcatraz, as a salute was fired, altogether made an exciting scene.

No repairs were necessary to the machinery of the "Peking" after her voyage. When in the dry dock her propeller was repaired and a number of defective rivets were replaced with good ones. Quite a number had to be removed, but this is what happens to nearly every iron ship after her first voyage. The engines and machinery of the "Peking" attracted a great deal of attention from our engineers. There is no reason why engines of like character could not be made here if occasion requires it. We gave a detailed description of the steamer when she was launched, and as so much has been said of her that we do not care to repeat it. The engines of course are very large. Each consists of two pairs of compound engines. The stroke is 54 inches. There are two low-pressure cylinders of 88 inches each, and two high pressure of 51 inches each. Either engine may be detached from the other, and in case of breakage of one of them at sea, the sound one may be worked while the other is in process of repair, and will propel the vessel at two-thirds of its regular speed. This colossal machinery is furnished with steam from ten cylindrical boilers, 13 feet in diameter by 10 feet 6 inches long, the shell of each boiler being 13-16 of an inch thick and double-riveted. Each boiler has three cylindrical furnaces, with 204 tubes 3 3/4 inches outside diameter by 7 feet 6 inches long.

On the excursion trip last Saturday, we examined with great interest the machinery at work. Standing over the cylinders there was not the least perceptible noise, and everything worked as smoothly as possible. In the engine room one could hardly conceive that the almost noiseless machinery was driving the enormous

CORRESPONDENCE.

Mexican Mines—San Dimas.

ENTRORS PRESS:—It has been some time since I have had the opportunity to post you on this and neighboring districts. The principal companies here are the Lsveaga's, the Durango mining company of New York, the house of J. Kelly & Co., of Msztlsn, and any amount of "buscones" (chlorides). The first own the San Luis mine, the Tapias, the Soledad and Arana mines. Fred. Sundell is their engineer. He put a two-mule whim into San Luis mine for them, which has done so much to remove their prejudice towards machinery, that they sent him to San Francisco to buy "Msquins" for the rest of their mines. They own the Hacienda of "Bsnarte," and they are the big guns of this region, holding the powers that be where the hair is short. In the meantime they are working only one quality at a time, until Sundell returns. They still adhere to the Mexican style of working ores, although Capt. Dahlgren's mill (rented to Storch & Co.) gives them ocular proof of the rapid dispatch and close working of ores, whether rebellious or not.

We now come to the second mentioned company, Durango mining company of New York. This company own the Bolanos, Candelaria and Cinco Senores mines, and the Hacienda of Huamuhil. This company bought these mines in 1864. Mr. Jos. G. Rice (now dead) was the first Superintendent. He started two tunnels, one for Candelaria and one for Cinco Senores. He worked the Bolanos mine and started the mill building of a 10-stamp mill at said Hacienda de Huamuhil.

M. Ralph Martin, of New York, was the second Superintendent. He advanced the two tunnels. In 1870, Capt. Dahlgren, of Nevada, succeeded him. He finished the mill and advanced the tunnels, starting a new one for Bolanos. Not being supported by his company, as promised, he got into debt and had to rent his mill for three years to get out, as also the Bolanos mine to Henry Janin and Thomas Bell, of San Francisco. Some troubles arose and things are mixed, although it is very evident that Dahlgren did not allow Janin to get ahead of him. There are all the elements of a fine lawsuit, etc. The mill was rented to Dr. J. B. Storch, of Austin and Eureka, and partners (Kelly & Co.). It has a dryer, crusher, self-feeder (Tulloch's), five stamps at present running; furnace of Dr. S. own idea, wooden pans, etc. The wheel is 50 feet diameter (overshot) and can drive twenty stamps if required. The Dr. has in 1½ years run worked up to 87½ per cent., and he gets more out by concentrating on "planillas," proving himself a first-class mill man, the only one in this part of Mexico. His loss is 20 oz. per ton of \$140 ore cost \$35 per ton, and they have shipped over \$100,000 (mostly bought ores).

The Candelaria is preparing to start up, as arrangements have been made for capital to push things to an early completion.

The Cinco Senores is in lawsuit with some jumpers, and Capt. Dahlgren is putting pumps into the Bolanos to drain it.

So just at present San Dimas is dull, but all indications are towards a speedy resumption of work and lively times.

The weather is cold for here, being 45° at 5 A. M., and as high as 80° mid day, dropping to 60° at 7 P. M. In San Vicente a Mr. Carson is pegging away at his mine with indifferent success. "On dit," that he has struck it lately—rich, very rich. The other district are holding the even tenor of their way.

"Tax."

Candelaria mine, San Dimas, Durango, Mex.

Utah Mines.

EDITORS PRESS:—Mining and smelting in Utah is this winter more lively than it has been any previous winter. In the Cottonwood, the Flagstaff is hoisting 60 tons per day of good ore. The Highland Chief, Wellington, Antelope and Prince of Wales are working and shipping quite lively.

In American Park, the Miller mine is working with 20 men and is taking out some good ore. In Tintio, the Eureka is working with 40 men who take out plenty of horn silver. The men receive a share of the ore instead of pay, which shows their good faith in the mine.

In Parley's Park, the Ontario is working under the able management of G. Hearsh as superintendent, with 25 men, taking out no ore but developing the mine continually. On the dump there have 1,000 tons of ore.

In West Mountain district, which is the most lively mining camp at present in Utah, the Neptune and Kempton mines working with 60 men, taking out from 30 to 40 tons per day. The Jordan and Galena are working with 60 men, shipping 50 tons of ore per day. This mine belongs to Carson & Bnzo.

The Utah concentrating works are not working at present on account of the difficulty of getting coal. The mine works with 10 men taking out 12 tons per day. The Rawling works with 15 men, taking out 15 tons of ore per day. The

Spanish Hill works with 30 men, taking out 40 tons per day. The Nez Perces Chief is working with 15 men taking out 20 tons of ore per day. They will soon be taking from 40 to 50 tons of ore per day. The Lsht Chance have run their tunnel 720 feet in and will soon strike the vein. The Ashland mine, owned by G. Hearst, works with 24 men and ships 20 tons per day. The Esst Last Chance, owned by Carson & Bnzo, is in 650 feet. All the other mines are working with energy, and some of them, as the Saratoga, Revere, Osceola, Lucky Boy, Washington and Royal have lately made rich strikes. The ore is most all carbonate, from 20 to 30 ounces in silver and 50 to 60 per cent. lead. From the other districts I cannot give you special information, as I have not visited them lately.

Climatic Changes in California.

At a recent meeting of the Californian Academy of Sciences, Dr. Henry Gibbons, Sr., read the following paper on climatic changes in this State:

An opinion prevails that the climate of California has changed since the American occupation, and that further settlement and cultivation will produce further changes. It may be well to inquire whether this be probable or, indeed, possible. The peculiar features of the climate of a country depend on two classes of causes, the one fixed and the other capable of change. The fixed causes are mountains and plains and permanent bodies of water. The changeable causes, such as man can modify or remove, are forests or the absence of forests, cultivation of the surface and drainage. The climate of California depends mainly on fixed causes. We have on the east the Sierra Nevada mountains, presenting to the winds an almost impassable barrier. Hence, east winds are almost unknown and will over continue so. On the west we have the ocean, with a constant current from the north, bathing the coast with water of the temperature of 52 degrees at San Francisco. Winter and summer this is the same. At high tide the thermometer plunged into the bay at Meigs' wharf shows this temperature in July as in January. Resting upon the ocean is, therefore, a body of air always cold. It follows that at all seasons, and under all circumstances, the sea breeze will have nearly the same temperature when it strikes the land. It is the great equalizer of temperature on the line of the coast, and wherever it can penetrate. Where the coast is skirted with mountains the ocean wind is walled out, just as the east wind is walled out by the Sierra.

Between the Coast mountains and the Sierra are other ranges running northward and southward, which also modify the direction of the atmospheric currents. The southerly storm winds of winter pour through the intervening valleys like water running in troughs, and, of course, take the direction of the valleys.

Our climate is modified also, to some extent, by the great deserts in the southern part of the State, and beyond. Those deserts become heated in the winter season, the superincumbent heated air rises, and its place is supplied from the colder regions of the northward. "Northerners" are thus produced. They are frequent in the southern counties, where they are called "sand storms" occasionally they sweep the whole State from its northern limit.

In the summer, when the valleys and plains throughout the State become heated, the air rises in like manner, causing the cool air of the coast to pour in at every possible break or depression in the mountain barrier, and to distribute itself through the interior following the lines of the valleys. Now, all these causes and conditions are permanent, and no amount of population or cultivation can change them. If man could level the Sierra, we might have east winds and a different climate, if he could remove the coast mountains, the sea breeze would sweep the State in its length and breadth. If he could, on the other hand, hold up the depression of the latter, and close the Golden Gate, we should have the climate of Arizona everywhere. If he could convert the Mohave desert into a garden, or wall it out by a mountain range, we might possibly get rid of our unwelcome northerners.

So much for the permanent causes of our peculiar climate. Now let us look for a moment at those causes which man can control or modify:

First. The removal of forests. This diminishes the rain fall, and renders the climate dryer and warmer, but there are no forests in California except among the mountains; and there a new growth of trees would spring up before the process of destruction would begin to tell on the climate.

Second. The drainage of marshes and lakes would have the same effect. But this is not likely to be done to an extent sufficient to produce tangible results, even if those results were desirable.

Third. The cultivation of the soil, by which a surface comparatively barren may be covered with verdure, would tend to render the air more cool and moist. But the difference would, in all probability be so slight as to exhibit no marked change of climate.

Fourth. The planting of forests, or patches and lines of trees, will have an effect similar to ordinary culture, and will also present a decided impediment to the surface winds. Most persons have noticed the increased force with which the wind blows over a raised causeway, or even over a wide and level plain. Many opportunities have been afforded in this State to witness the effect of an orchard in warding off

the sea breeze for some distance to the leeward. This process, it is true, would not produce any change in the general climate, but it might be employed in proper localities to serve the interests and comforts of the inhabitants, and to protect them in a measure both from the rigor of the ocean wind and from the drying and blighting influences of the northerly gales.

In contemplating this subject I can discern no other influences by which our climate can be changed than those above enumerated. It is evident that no radical change can be induced by those agencies; but it may be alleged a spontaneous change is going on irrespective of local conditions and causes. We have no warrant for this supposition in the history of older countries. It is more than probable that a gradual change is going forward in the climate of the whole earth, but so slowly that centuries of carefully made and renewed observations, will be required for its demonstration. Any change which takes place within a period of fifty years at any point should be regarded as a temporary oscillation, or a portion of a circular revolution.

My conclusion, therefore is that the climate of California and the adjacent territory is undergoing no permanent change; that no such change is possible; that the winter season will continue to give its rains in uncertain quantities; that the dry season will continue to be dry; that summer and winter, seed time and harvest will continue to succeed each other with no essential deviation from the general type as observed since the American occupation.

A rich vein of cinnsbar has been discovered by S. W. Payne, on Point Reyes, Marin county. Quicksilver has been found by retorting the soft clay of an ochrous color, which lies between the rock. The vein runs north by west to southeast, and has been traced about eight miles. There seems to be several minerals in the ledge. W. O. L. Crandall found two small buttons of silver by the rude process of roasting the rock.

THE Calaveras Chronicle says the running of a tunnel through the ridge that separates Cook & Co' hydraulic claim on Sport hill, from the ditch is completed and being used for conducting water to the mine. The tunnel drove for the reception of the sluices is also finished and the flume laid. The claim is now in prime order for working to advantage, and operations are being pressed with vigor.

WITHERILL, of Benton, Inyo county, has made a sale of his mill and mining property to a San Francisco stock company, receiving therefor \$65,000. Last summer, in a five months' run, the selling party realized \$55,000 from the same mine; but he sells it with the avowed intention of finding something near by equally as good.

THE hoisting machinery of the Black Diamond coal company's new shaft at Nortonville, which has been thoroughly refitted since the disastrous fire, some four months since, was tried with steam last week, in preparation for the business of hoisting the coal from all the workings through the new shaft.

BETWEEN Coso and Little Lake are several famous springs or mud volcanoes. These have been located by A. B. Elder and others, principally on account of the vast deposit of brimstone, of which it is said no less than 10,000 tons, almost pure, can be collected there.

THE suit of Creed Haymond against the Spring Valley canal and mining company, for the sum of \$9,700 was settled at Oroville last Wednesday by arbitration. The matter was referred to Judge Sexton, Judge I. S. Belcher and P. O. Hundley, and the sum allowed was \$3,500.

A NEW and rich quicksilver mine has recently been discovered on Mr. Brannan's land, two and a half miles west of the Calistoga railroad depot, and not a little excitement has been created thereby.

THE work of running the 1,000-foot level in the Gwin mine is progressing finely. Indications are good that the level is approaching the pay chute. In the meantime good ore is being mined in the 900-foot level, upon which the batteries are kept busily employed.

THE mining excitement in Potter valley is running high. They have found gold, silver and quicksilver. It is said there is not a foot of the hills surrounding the valley, north, east, west, or south but what has been staked off for a mining claim.

JOS. GINACOA, Superintendent of the Humboldt mill and mining company's works at Winnemucca, Nev., has leased the Tullula mine in Dup Glen for eighteen months. He intends to commence operations on the mine about the first of March.

A RICH strike is reported in the Hussey mine at Cornucopia. The mine referred to is the first location north of the famous Leopard mine, and work, which has been suspended for some time past, had only been resumed some three or four days before the strike was made.

A SAN Fernando correspondent writes to the Call confirming the reports of rich cinnsbar discoveries in that vicinity, and states that all that is now needed is capital with which to develop the mines.

MINERS near Quincy are making good wages.

Nickel Mine in Napa County.

We have lately referred to new discoveries of copper and chrome iron in our neighborhood and have endeavored to show up the many advantages to our citizens to be derived from the working of these newly found deposits, and the sure influx of a large immigration to our county as a necessary sequence to the developing and working of our mines, of whatever kind they may be. The latest new discovery is that of nickel. Mr. Finley, who has been prospecting for the last few years, while in the neighborhood of Pine Flat a few days since, discovered an immense ledge of this metal, which may be added to the many mineral productions of our section of country. The value and usefulness of this metal cannot be overestimated. Its uses are various, principal among which is the manufacture of our new American cent coin, of which twelve parts in one hundred are nickel and eighty parts copper. Aside from this newly found ledge in our neighborhood, we believe there are but two other mines in the United States where it can be obtained; one is in the State of Connecticut and the other at Lancaster, Pennsylvania; the latter being the mine which supplies the nickel for our new one-cent coin. It is also used for making needles for the compass, having the advantage over iron, inasmuch as it does not rust. This metal would be more generally used in the various arts, judging from its adaptability for many purposes, if it were more generally known, and if larger quantities of it could be procured. Other metals, such as iron, lead, cobalt, copper, together with sulphur, are usually found in small quantities where this metal is procured. Ores of a similar character have also been discovered in North Carolina, but as yet no great development of the ledges have been made. Missouri also claims to have some discoveries of this ore, but the proof of its existence is yet wanting. We have most unbounded faith in the recent discovery of nickel in our vicinity, and, like our copper and chrome iron mines, it only needs a little capital in conjunction with labor to unearth and bring to light another source of great wealth to our State. This discovery is situated about two miles from Pine Flat, and near the Occident, Brother Jonathan and Woodpecker quicksilver claims. The assay of the latter shows the presence of copper, and as this is usually found in conjunction with nickel, and as all three of these claims are in close proximity to the recent discovery, we see no reason why we should not infer that the region in which these claims are situated should not contain nickel in large quantities. Nothing is now wanting but capital to develop.—*Calistoga Press*, Feb. 13.

PEAVINE.—The most encouraging reports are coming in from the Peavine mines. The Consolidated Peo are crushing ahead without interruption, both as to the mill and McGlew furnace. They both work to a schism. Their average roasting of ore daily is only five tons, owing to the bad quality of wood that is being used; otherwise the yield of bullion would be larger. The last thirty-six hours retorted bullion to the amount of sixty pounds, showing a fineness of 980, and a yield of over \$60 per ton of ore. In a very short time this company will be clear of all liabilities, and run the mine and mill without assessments. The daily yield of ore from the mine is over thirty tons of good pay ore. The Golden Fleeca mine is producing a very high grade of pay ore out of the incline, which is down to 70 feet, from the 156-foot level. The bottom of this incline contains the whole width of this fine grade of ore—over three feet. The average assay of this ore is over \$300 per ton. They have contracted with the Auburn mill company to crush a few tons by Stetefeldt process, during the coming week. There is prospecting going on on all claims which can be worked under cover much more activity of working the several claims would prevail if the heavy snow was not a barrier to the sinking of open shafts. Already every preparation has been made to start up in full earnest the moment the state of the weather will permit.—*Nevada State*.

SHEWD miners and traders are already making active preparations for another assault upon the treasure vaults of Cassiar, although there seems every reason to apprehend that King Frost will keep them back later than usual. Upward of 2,000 went there last year, and probably more than double the number will go this year. We do not think, however, that many from California will go there, as the reports of the country last year with regard to climate and possibilities of work, were sufficient to warn people in this State to stay at home.

THE RAILROAD car shop of Sacramento, is running all its machinery, and there are good prospects for plenty of work. They are busy in the paint shop also with a full gang, an altogether, the indications are that the company will have a large force employed this season.

A CAT fell down the shaft of the Minnesot mine at Fairview, Idaho, a few days ago, a distance of 800 feet, and on being sent to the surface, sprang out of the bucket, apparently uninjured.

A LARGE number of new mining enterprises have been inaugurated in the vicinity of Silver City.

GLOWING reports are received from the silver copper and iron mines in Soledad canyon, Los Angeles county.

SCIENTIFIC PROGRESS.

A Layer of Hydrogen Above Our Atmosphere.

In a paper read before the Manchester Literary and Philosophical Society, Henry H. Howorth observes: "It is clear that if under certain conditions hydrogen be an exception to the general law of the diffusion of gases, and follow rather the more general law of gravitation, it will exist in a stratum above the atmosphere and beyond the reach of direct observation. In his experiment upon the occlusion of gases, Mr. Graham examined several aerolites and found that under the air pump, they parted with a very large quantity of occluded hydrogen. If, as is probable, the gas was occluded by the aerolites when at a red heat, and this red heat was coincident with their passage through the layer of the upper atmosphere in which the phenomena of the shooting stars and of the aurora occurs, it seems more than probable that this stratum is a layer of hydrogen. This is confirmed by what we know of the spectrum of certain auroras, which resembles those of the zodiacal light and the solar corona. The spectrum of the corona has been the most attentively studied, and Janssen, perhaps the greatest authority on it, speaks most confidently about its distinguishing feature being the hydrogen lines, while a special line which characterizes both its spectrum and that of aurora, and which is different to that of any terrestrial substance, is considered by Father Secchi to be an abnormal hydrogen line. Dr. Dalton long ago argued, as Mr. Baxendell has reminded Mr. Howorth, that the peculiar features of the aurora could best be explained by the hypothecon of a stratum of some peculiar gas above the atmosphere. A gas of a 'feruginous nature' is the expression of Dr. Dalton. Now, hydrogen, in the higher chemistry, is not only closed among the metals, but Faraday and others have shown that in its relation to magnetism it is nearly allied to iron. So that a stratum of hydrogen above the air would seem to exactly answer Dr. Dalton's postulate. If it should exist the earth would resemble the sun in one remarkable feature; for we now know that the sun is girded with an immense layer of hydrogen. Lastly, he would add that the heterogeneous texture of the great nebula in Orion seems to argue that the law of the equal diffusion of gases does not prevail here.

Gases Evolved from Molten Iron.

The author considers that gases evolved from molten iron come from three sources. 1. They were dissolved by the iron while melting in the furnace. 2. They were dissolved by contact of the molten iron with the air. 3. They were dissolved by contact of the molten metal with the mould.

1. The evolution of gas from gray iron is small; the gas consists chiefly of hydrocarbons or carbon iron oxide. From white iron more gas is evolved, together with little particles of iron, which are oxidized in the air. Spiegel-eisen evolves a peculiar white fuming gas, which contains silica, and is probably silicon fluoride.

The author thinks that the poorer an iron is in combined carbon, the more readily does it absorb gases containing carbon, while the richer it is in carbon the more readily does it dissolve gases containing hydrogen. The primary cause of the evolution of those gases which have been dissolved in the furnace he traces to the diminished pressure under which the iron exists, as compared with the pressure in the furnace.

2. By the action of the air, the surface of the molten iron becomes oxidized. In iron containing much carbon, the oxygen is transferred from the air by means of the metallic surface to the carbon, which it oxidizes to carbon monoxide, which again bubbles up through the molten mass; hence it is in such irons that we find the greatest amount of blisters on the surface after cooling. White irons show fewer of these, and spiegel-eisen solidifies with a smooth surface.

3. As the mould into which the molten iron is run always contains water, this water is vaporized by contact with the liquid iron, the steam thus generated is partly given off as gas, and partly decomposed, hydrogen being evolved and iron oxide being formed. Again, if the iron contains sulphur, this, by reacting on the steam, will form sulphuretted hydrogen, which is often formed in the cooled iron.—*A. Ledebur, Chem. Center, 1873, 810.*

FLUIDS IN CRYSTALS.—Dr. Carmichael, in a paper on the "Growth of Crystallization in Treps and Slegs," stated that in 1820 Worcester found in diamonds and chrysoberyls a fluid, and in some cases two fluids, having an expansive capacity thirty-two times that of water. Examined microscopically these liquids were found to exist in the minute cavities of various rocks. Dr. Carmichael stated that he himself had made many examinations of slags from the Hartz mountains. These crystals were no doubt formed with great rapidity, and this fact in part accounted for the finding of aqueous solutions in the center or cavities of crystals. In the genuine trap rock liquid (carbonic acid) inclosures are found, sometimes with minute traces of watery vapor. Gas cavities have broad margins, the vaporous cavities thin margins.

Science Among the Ancients.

One of the most important discoveries ever unearthed is probably the library of Assurbanipal, who reigned over the kingdom of Assyria about 1,000 years before the Christian era.

This discovery furnishes the most undoubted proof that science had made considerable progress, even at that early day—nearly 3,000 years ago. This curious library consists of flat, square tablets of baked clay, having on each side a page of closely written cuneiform letters which had been impressed on the clay while it was yet moist. The great majority of these tablets are now in the British Museum, and have been found to contain the remains of an immense grammatical encyclopedia. There are fragments of many mathematical and astronomical treatises, with catalogues of observations, tables, calculations of eclipses of the moon, and observations of solar eclipses, the earliest of which occurred nearly a thousand years before the beginning of the Christian era. There are also fragments of law books and legal records, books of chronology, manuals of history, accounts of Assyrian and other divinities, collections of hymns in the style of the Psalms of David, a geographical encyclopedia, works on natural history containing lists of plants and animals, of timber trees employed in building and furnishing, of stones fit for architecture and sculpture, etc. Perhaps the most interesting of all these lists is a classified catalogue of every species of animals known to the Assyrians, showing a scientific nomenclature similar in principle to that of Linnaeus. Opposite the common name of each animal is placed a scientific and ideographic name, composed of two parts, a family name and a characteristic epithet denoting the species.

A still more remarkable indication of the scientific advancement of the ancient Assyrians appears in their system of weights and measures, in which, as in the French system, all the units of surface, capacity, and weight were derived from one typical linear unit. The basis of the system was the cubit (equal to 20.67 inches). This was divided into sixty parts, corresponding with the minutes of the degree. The cubit, multiplied by 360, the number of degrees in the circle, produced the stade, the unit for large distances. The fundamental unit for areas was the square foot, the square of measure bearing to the cubit the relation of 3 to 5, or 12.4 inches of our measure. The cube of the foot was the metreta, the standard of all measures of capacity; and the weight of a cubit foot of water gave the talent; the fundamental unit of weight; the sexagesimal division of the talent gave, first the mina (=510.83 grains), and second, the drachma, (=8.51 grains).

The sexagesimal system was employed throughout their mathematics, the unit being invariably multiplied or divided by sixty, the result again by sixty, and so on to infinity. "This, it is very evident," observes Lenormant, "was the result of a wise combination of a very practical character, intended to combine the advantages of the two systems of dividing unity that have been in dispute at all times and among all nations—the decimal and the duodecimal." We still follow this Chaldeo-Assyrian system in the divisions of the circle and in our divisions of time.

ALUMINIUM FOR ENGINEERING INSTRUMENTS.—Mr. S. B. Clevenger recommends the use of aluminium for engineers' instruments, its great recommendation being that an equal bulk weighs but one-fifth as much as brass, an ordinary transit weighing 11 pounds in brass, weighing but 3 pounds in aluminium, and within the limits of practicable weight such instruments could be made very much larger and more accurate than in any other metal. Aluminium costs about half as much per pound as silver, and does not rust or tarnish so easily as brass. It combines the ductility and malleability of copper with vastly more than the strength of steel (it is placed by some as thirteen times stronger), and the lightness of chalk.

IMPROVED CHROMO LITHOGRAPHIC PROCESS.—Messrs. Johnson, of Hatton Garden, London, have invented a new and economical process for producing chromo-lithographs. In place of using a special stone for each color, necessitating so many separate impressions as there are colors, the entire subject is drawn upon a single stone and a proof is taken on a thin sheet of copper. This sheet is then cut out carefully according to the desired contour of the colors, and upon each of the portions is fixed a solid block of color previously prepared. The whole is combined into one form, and is printed on an ordinary press—all the colors at once.

EVAPORATION OF WATER FROM PLANTS.—So great is the evaporation of water from plants that it was found by Mr. Lawes that a plant of barley of one hundred and seventy-two days' growth, in which it had acquired four hundred and nineteen grains of dry organic matter, had converted into vapor not less than seventeen pounds of water.

OPTICAL PROPERTY OF CRYSTALS OF SULPHATE OF COPPER.—If we receive the solar light reflected by a large crystal of sulphate of copper upon a sheet of platinum or tin plate, placed at a small distance from the crystal, the sheet assumes the color of metallic copper upon the part which receives the reflected light.

MECHANICAL PROGRESS.

Sand and its Effects in Mortar.

We extract the following from a report made by some eminent French engineers, who made a series of scientific and practical examinations of sand, and the effects of different qualities of the same on various kinds of mortars:

The primordial element of sand is quartz. Rocks composed of felspar and mica cemented together by natural affinity, produce many varieties; some are derived from gneiss, protogine, or talcose granite, sienites, etc., or are entirely calcareous; lastly, others are mixed with volcanic sand, but these do not possess any of the qualities of puzzolana.

Sand is designated as coarse, middling, fine, and very fine.

It is considered coarse when the grains have a diameter of 1-12th to 1-18th of an inch; and it is called fine when the grains do not exceed 1-25th of an inch. That which exceeds the former diameter is called gravel.

Besides river and sea-sand, we have those which are found away from water sources, known as fossil sands, of the plain, or quarry sand; but these must be distinguished from the true fossil sands, which are called *arenas* in France.

Fossil sand (that found in hill deposits) is far more irregular in the grain than either river or sea sand; it is far more gritty when the grains are strongly compressed between the fingers; quartz and granite dominate in their composition.

In the composition of mortar, sand forms the inert matter; it exercises no chemical action on the lime, the puzzolanic constituents, and the mortars with which it is mixed; its action is purely mechanical, and consists in the aggregation of the grains by the aid of the lime and cements, which perform the part of mordants, or active agents of cohesion; it follows that the sand of which the grains are angular and the angles the sharpest, are preferable to those with rounded grains, or of which the asperities are less numerous.

The various kinds of sands should be hard to touch, gritty to the fingers, exempt from earthy matter, which causes disaggregation of the mortar by humidity; and for the same reason, though to a less degree, marly or clayey sand should be rejected.

In the case of sea sand, the first thing to be done, is to get rid of the salt. The presence of salt, however, may be very useful in certain cases.

It is of great importance to take careful note of the various results obtained by the use of different kinds of sand found where works are being carried on; some kinds contribute powerfully to the cohesion of mortars, in combination with certain kinds of lime, while others are the cause of disintegration. Experiments of this kind cannot be too numerous or too carefully conducted.

M. Vicat instituted a series of experiments in order to determine the effect of the coarseness or fineness of eminently silicious sands, or the resistance of mortars, and arrived at the conclusion that for use with eminently hydraulic lime, sand ranks as follows: 1, fine grain, 2, sand with mixed grain and sharp angles; 3, coarse sand; while in the case of moderately hydraulic lime, the order is reversed, the coarse standing first, the mixed second, and the fine grain last.

Results since obtained with other kinds of sand, have fully borne out M. Vicat's conclusions.

The mixture of lime and sand is the more complete, and the aggregation the more intimate, in proportion to the roughness of the grains; river sand, which has been extracted and left on the banks for many months, and having its surface corroded by natural agents, are beyond all question the best; but those of the quarries, which are best when their composition is very silicious, offer much the same advantage in practice.

Mortar made from quick-lime and coarse sand is the most durable; fine sand acts best with hydraulic limes. In the case of hydraulic mortars, the definite setting with middling-sized sand being fixed at 100, the proportion will descend as low as fifty with gravel, and even lower when it is very coarse.

Quartzose and silicious sands are insensible to the most powerful compression. This quality has caused them to be sought for paving-work; and they are preferred before all others for foundations, and in all cases where great pressure has to be considered.—*Manufacturer and Builder.*

MECHANICAL PUDDLING IN ENGLAND.—There seems to be considerable dissatisfaction in the north of England (Cleveland) iron district, with regard to the working of the Dank's furnace, and the iron workers are just now in the throes of the Crampton furnace; and it is being employed to improve upon the Casson-Dormoy furnace. Nothing definite, however, has as yet been accomplished, though it is said some experiments which Mr. Crampton has made with Cleveland pig iron encourages them to anticipate that the change from the Dank's to the Crampton will prove a wise one. This opinion should doubtless be received with much doubt, as coming from those to whom the wish is father to the thought.

Paint for Iron Surfaces.

A writer in the *Painter's Magazine* says that the best linseed oil, with all its advantages, is but poorly adapted to long service as a protection to iron surfaces exposed to extreme variations of temperature and to all kinds of weather; but that in selecting a paint for such purpose, mechanical adhesion is a consideration of the first importance. In this respect, paints differ widely, but it must be remembered that, mechanical adhesion is all we have to depend upon. With absorbent surfaces it is different. Professor Williams gives it as his opinion, based on observation and experiment, that pitchy or bituminous films are especially effective as regards their adhesion to iron; for example, solutions of asphalt or pitch in petroleum or turpentine. These are also very effective as regards continuity, owing to the fact that, in drying, they form plastic films, which yield to the expansion and contraction of the iron, and manifest no tendency to crack. If the surface is rusty, they penetrate the oxide scale and envelop the particles very effectually, making them a portion of the paint. The solubility of such a film in water may be counteracted by mixing it with linseed oil. The experiment may easily be tried by mixing about two parts of Brunswick black with one of white, red, or colored paint, the body of which is composed of red or white lead or litharge. Red lead is the best for many reasons, if finely ground and thoroughly mixed with linseed oil. Any of several kinds of bitumen may be used, either natural mineral asphalt, pine pitch, or artificial asphalt, such as gas tar or the residuum of petroleum distillation in cases where the crude oil has been distilled before being treated with acid. This gives a very hard, bright pitch, which is soluble in "one run" paraffine spirit, and which makes the base of an excellent, cheap, and durable paint for iron work in exposed positions.

During the past few years, the writer has heard many accounts of the preservative influence of paraffine when applied to iron surfaces, and can recommend it for all classes of iron work which can be treated hot. The most effective method of applying it is to heat the iron in vacuo, in order to expand it and open its pores, when paraffine, raised to the proper temperature, is run upon it. By this means the iron is penetrated to a sufficient depth to afford a very effectual protection against oxidation, especially when a suitable paint is subsequently applied. Any non-oxidizable substance would probably answer; but paraffine is as cheap as any and quite as good if not better. Brushed upon the outside merely, it is doubtful if paraffine would have much effect in preserving iron, while it would certainly lead to lessen, if not destroy, the mechanical adhesion of a surface paint.

LOCK AND MORTISE BRICKS.—On the score of ingenuity, one of the most prominent features is the process by which the lock and mortised bricks are obtained at the Serr Terra Cotta works, near Waterbury, Salop, England. The machinery itself will be readily appreciated when the fact is borne in mind that the bricks, while producing workmanship infinitely superior to walls built with pressed bricks, being tongued, grooved and locked at intervals, and at each angle, are also stronger than common hand made brick, besides possessing the additional recommendation of effecting a saving of two-thirds in the material used. These lock and mortised bricks, it may be added, are capable of extensive and varied uses, and are invaluable where space and height, with solidity, are an object. Their importance is especially noticeable when required for the building of, or sustaining and retaining, embankments, sea and other walls, quays and river frontages, as also in the erection of shafts, the construction of brewers' vats, and, in a word, the formation of all works to which brick can by any possibility be applied. The company also produce Kongh's universal ventilators. The mechanism applied, is of a unique description; and it is necessarily exclusive.

MAONETTO IRON SANDS.—The vast deposits of magnetic iron sands in various parts of the world promise soon to become of great industrial value. These sands from New Zealand have long been worked to much advantage, being transported to England for treatment. The extensive deposits in Labrador are also beginning to excite much interest, and several companies are now engaged in collecting and shipping them to England. About 30 tons are collected daily at one single locality. The separation of this sand from other substances mixed mechanically with it is now greatly facilitated by the use of a new magnetic ore separator, which has also been used to advantage in other localities.

The sand thus separated are roasted and then converted into a magnetic oxide, from which the iron is easily extracted. It is well known that extensive deposits of magnetic iron sands are found on the sea beach for some distance to the south of Fort Point, along the western outskirts of this city. It is confidently believed by many that these sands may at some future time be profitably worked in this city.

RECIPE FOR A CEMENT FOR MENDING STEAM BOILERS.—Mix two parts of finely powdered litharge with one part of very fine sand, and one part of quicklime which has been allowed to sleep spontaneously by exposure to the air. This mixture may be kept for any length of time without injuring. In using it a portion is mixed into paste with linseed oil, or, still better, boiled linseed oil. In this state it must be quickly applied, as it soon becomes hard.

Mining Stocks.

We are still calid upon to wirts the same sentence concerning mining stocks, that we have for the past six wssks, viz. that the market continues dull. Transactions are limited, and nothing at all but Consolidated Virginia holds its own. Everything else is down and no buoyancy at all is manifest. Some little attention is being again turned to the Ely District stocks, but there is no excitement in them. All the Washoe line of mines continue very dull, and the brokers business must be poor just at present. Every now and then some stock will take a little spurt upwards for a few days, but no general advances has taken place for some time. All the operators seem to be lying on their oars, and waiting for something to turn up. The market will no doubt "wake up" again some time but whether within one month or three months no one can tell. At present, however, very little is being done.

A VERY useful arrangement has just been adopted at Brussels. Any traveler from Paris to that city may purchase a railway ticket which will include the hire of a good carriage to take him and his luggage from the Brussels station to his destination within that city. The advantage is that he is saved all trouble in looking for a cab, and all annoyance in squabbling with the cabman about his fare.

The North Bloomfield gravel mining company in Nevada county, has been at work for four years and has not yet fairly commenced washing. The total expenditures on the claim have been \$1,979,760. The tunnel, which is nearly 8,000 feet long, consumed \$498,000 of this amount, and \$1,081,000 has been spent for ditches, reservoir, water rights, etc.

Advices from Castle Dome, Arizona, say H. W. Keering has succeeded in making a fine run at the smelting works there, and has demonstrated beyond doubt the feasibility of reducing those refractory ores without shipment to San Francisco, as formerly.

The San Diego Union reports that all the mines in the Julian and Banner districts are looking well, and that the quantity and quality of the ore is steadily increasing. Work is going forward with greater activity than ever before.

The Quincy National says: "Many of our hydraulic miners depend almost entirely on the snow water, and unless the weather changes soon, and the stream hold out much longer in the spring than usual, the water season will be unusually short."

The inventor of the McGlew furnace must feel happy over the success of this invention in Peavine District, Nevada. Peavine ore has been difficult to work, but the McGlew furnace has demonstrated the fact that they can be worked with profit.

DURING the past year, 81,397 tons of coal were shipped from Nanaimo, 15,197 of which went from the Vancouver coal company's mine, and 30,200 tons from the Wellington mine.

ABOUT 75 miners for Sticken left Victoria by the "California" week before last for the mines.

THE LA GRANGE ditch and hydraulic mining company, says the Modesto Herald, located at Le Grange, Stanislaus county, has at last got to paying handsome dividends. This company was organized four years ago, and is composed of San Francisco capitalists. Its invested capital is \$600,000, and it disburse about \$9,000 per month in the way of expenses. It works a force of 90 men, and operates over an area of 500 acres. It owns the most extensive, expensive, and substantial ditch in the county, being 17 miles in length, and costing \$500 per rod.

COPPER.—We see by James Lewis & Son's monthly Liverpool report on ore and metals, that the copper market is very dull and inanimate. Quotations on the 1st inst. were; bars, £83 to £85 10s according to brand; ingots, £89; ore and regulus, 16s 3d to 16s 9d per unit. The Chili exports to January 17th, were 55,859 tons fine. Stocks of West Coast produce are estimated at 12,242 tons fine, against 11,765 tons on the 1st of January.

APPROPRIATIONS FOR CALIFORNIA.—The River and Harbor Bill, which has passed Congress, appropriates \$100,000 for the improvement of Oakland harbor; \$80,000 for Wilmington; and \$15,000 for removing snags from the Sacramento river. San Diego gets \$80,000 for turning San Diego river into Pelee Bay, instead of allowing it to deposit sand in the bay proper. This, however, is small consolation to San Diego after the Texas-Pacific defeat.

The Redington quicksilver mine shipped 141 flasks during January, a far smaller amount than usual, owing to the bad condition of the roads.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

THE NEW QUICKSILVER SMELTING WORKS.—*Amador Dispatch*, Feb. 20: We are happy to be able to state that the new smelting works at the Amador quicksilver mine have been completed and were set into active operation last Monday. We hope to be able before many days, to give our readers a favorable report as to the richness of this mine, after being practically tested; and, judging from the various specimens of ore we have seen taken from this mine, we have no doubt as to the result.

SMELTING PROCESSING.—*Amador Ledger*, Feb. 20: The Cosmoss ditch, owned by Judge Purinton of Fiddletown, has been extended to the Gover mine, and to Quartz mountain, and will supply the Gover mill and the mills hereafter to be erected at Quartz mountain with water to propel the same. From these localities the ditch will be continued west to furnish water for other mills and mines. The extension of the ditch above named, will open up extensive gravel claims along the line of its extension, and will give a new impulse to mining in that part of the county.

NEW DISCOVERY.—In the tunnel now being driven by Messrs. Trueb & Billiard, in their claims, adjoining the Martell, a channel of very fine gravel has been recently struck, which promises very rich results. This channel is evidently a separate one from all others heretofore discovered in the ridges, and as far as proven, seems to be more extensive and richer in gold than those tapped by other tunnels driven into the same hill. The newly discovered channel seems will run through the claims of Trueb & Billiard, and the Martell claims, the latter owned and worked by the Amador canal and mining company. The discovery of the new channel will add greatly to the value of claims through which it may pass.

CALAVERAS COUNTY.

GRAVEL MINING.—*Calaveras Chronicle*, Feb. 20: All the hydraulics in this vicinity are in full blast. The ditch is taxed to its utmost capacity in conveying water enough for the various claims, making things lively in the mining line. Several new enterprises are about being undertaken, and everything be-appears unusual activity in gravel mining operations.

GOOD CLEAN UP.—A late clean-up at the Mullins' gravel claim, near Central Hill, yielded one hundred and sixty ounces of gold. The result of four weeks' work of four men.

WORK RESUMED.—Work has been resumed on the old Vance mine at Mosquito. The ledge was one of the earliest discovered in that district and has yielded a large amount of bullion. THE VALENTINE MINE.—We learn that the Valentine mine, in Mosquito district, has been re-located under the provisions of the Mining Act of 1872, and that work upon it is now going steadily forward. The Valentines is, we believe, the pioneer mine of this district.

THE LEWIS & FAIRCHILD MINE—GOOD YIELD.—Last week we briefly chronicled the recent discovery of a very promising quartz ledge, near Leavitt's ranch in the Mosquito district, by those well known miners and prospectors, Messrs. Lewis & Fairchild. Since then, thirty-odd tons of rock taken from the ledge have been crushed in Garland's mill at Mosquito. The ore yielded an aggregate of eighty-four ounces of gold—an average of nearly \$50 per ton. But little work, comparatively speaking, has yet been done upon the lead, but this prospect is altogether favorable for the development of a valuable mine. The ledge averages fully two feet in width, while the result of the crushing, stated above, establishes the character of the ore for richness.

CONTRA COSTA COUNTY.

QUICKSILVER NEAR CLAYTON.—*Antioch Ledger*, Feb. 20: While the adjoining counties across the bay have been making rich developments in silver, quicksilver and other precious metals, there has been some prospecting on Mt. Diablo and vicinity, and not without success. A few days since, a well defined lead of quicksilver was found on the ranch owned by Mrs. Hastings, widow of the late Liman Hastings. The location is within two miles of Clayton. C. P. Marsh, of Oakland, Harry Morse, Sheriff of Alameda county, Mr. Calderwood, his deputy and one Spaulding, have purchased the ranch of widow Hastings, rumor says, for five thousand dollars. The vein of quicksilver is said to be the best defined and richest of any yet discovered in the county.

EL DORADO COUNTY.

NEW MINES.—*Folsom Telegraph*, Feb. 20: In El Dorado county, near the line of the railroad about Sugar Loaf mountain,

Feb. 20: Richer and better and more of it, is the report this week from New York Hill. Mr. Meek, late cashier of the bank of A. Delano and one of the executors of the estate, showed us some of the finest specimens one day this week that it has ever been on lot to examine. One piece, estimated to weigh about two pounds if all quartz, actually weighs over four pounds, and therefore must contain something like \$425 in gold. This was from the lowest depth reached and a direct continuation downward of the rich bonanza struck some weeks since.

DARTMOUTH.—We visited this mine, just out at the north end of Church street, this week and found both mill and hoisting works at work. For several weeks past they have been taking out of the drifts a lot of waste stuff left there in previous workings, and as this was soft enough to wash out in ordinary sluices the mill has been idle for some time. This old waste gave a clean-up of \$1,140 from a two weeks' run, and on the return of Captain Miller, the Superintendent, from below, it was thought best to put what is now coming out through the mill, as much of it was cement. Capt. Miller is fast getting the Dartmouth in shape for a splendid run.

THE GOLD TRAP of Mr. Tuubridge, having proved itself capable of saving gold from the tailings of the Empire Mill—which saves \$60 a day by the use of Hendy's Concentrator above the "trap" but below the point at which many mills let all go to waste—is now stationed on the gravel alluvial below the Dartmouth works, out on Church street.

PLUMAS COUNTY.

STUCK IT.—Plumas *National*, Feb. 20: We learn from Deputy Sheriff Yeales that the American Company of Washington Hill, (Flagg, Durrell & Co.), recently struck gravel which prospects first-rate. They got one nugget which weighed half an ounce. This company have been running in bed-rock for the past two years, and deserve to have the best kind of pay. We hope the strike will prove rich and extensive.

SIERRA COUNTY.

PAYING.—Mountain *Messenger*, Feb. 20: The diggings on Badger Hill are paying very well just now, and the rich bank of ground recently discovered, promises to hold out for some time to come.

ORO.—It is now a dead certainty that work on the new Oro mill, just above town, will be commenced at an early day.

WATER.—Westall & Co., of Poverty Hill, have enough water to pipe about eight hours every other day, which is better than no water at all.

A new claim has been located near the Iowa claim in which pay gravel was recently struck.

SONOMA COUNTY.

RICH STRIKE.—Petaluma *Argus*, Feb. 19: We are informed that the Eastern Quicksilver mine, near Guerneville, has recently made a strike of some very rich cinnabar. The company has been running a tunnel parallel with the ledge for several months, and are now in over one hundred feet. The mine is supposed to be very rich, but the owners refuse to admit the public in the tunnel. The Western company are also taking out some very rich rock, and the people of Guerneville are happy.

ABE LINCOLN.—The Abe Lincoln silver mine, located a few miles northwest of Healdsburg, is creating quite an interest among our local mining sharps. The company have sunk a shaft on the mine some fifty feet deep, and drifted on the ledge forty-five feet in one direction, and fourteen in another. The ledge is well defined, and three and a half feet thick, standing at an angle of forty degrees. The rock taken from the ledge twelve feet down assays \$24 per ton, and specimens that have been picked run as high as \$80 to \$120 per ton.

Henry Miller has found a quartz ledge on his land near Guerneville, from the croppings of which an assay has been made, showing silver and gold in small quantities—enough to justify him in prospecting the vein.

The Ida Clayton mine, which is situated in Knight's Valley, is looking well. Its superintendent is Charles Ridgeby, an old Napaite. Fifty men are employed at the mine, and they are getting out some very good ore. In a seven days' run they got thirty fisses of quicksilver. The workmen have struck a body of black ore, which is one of the richest of cinnabar formations.

SISKIYOU.

TRAMWAY.—Yreka *Union*, Feb. 20: We understand that the Black Bear mining company talk of building a tramway for the purpose of carrying their rock from the mine to the mill. The distance which the rock has to be taken is about two miles. To perform the work several teams, with drivers, are required. The grade from the mine to the mill is so descending that loaded cars will run from the former to the latter without other force than that of gravity.

CINNABAR DISCOVERED.—From Richard Smith we learn that some rich cinnabar was discovered on the Klamath, near the mouth of Horse creek, last week. The discoverer was Eli Miller. It seems there is a peculiar formation, or ledge in which small veins of cinnabar alternate with the common rock. This formation is about one hundred feet in thickness, and was discovered first on the north side of the Klamath, in the point formed by the junction of Horse creek and the Klamath. It was afterward found on the south side of the river, maintaining about the same width and exhibiting the same appearance and characteristics. Smith said the veins of cinnabar through this formation were numerous but small. There

was no one there who had had experience in quicksilver mining, but with improvised retorts they were able to obtain an abundance of quicksilver. The discovery had caused quite an excitement, and several were prospecting in the hills in the vicinity.

TRINITY.

CINNABAR DISTRICT.—Trinity *Journal*, Feb. 20: B. C. Wattles came in this week from Cinnabar district, and reports further rich developments. As to the district at large, Wattles is of the opinion that it contains more wealth than all the remainder of the county. As far as ascertained the main lode of cinnabar is from one-half to one mile in width, and has been found at irregular intervals for a distance of three miles in length. Lytle & Hawket, with two men, are taking out ten tons of ore per day, which will work on an average of 25 per cent. Worland & Butler are working concentrated ore which gives 80 per cent. The Trinity quicksilver company are in a little over 200 feet in their prospecting tunnel, the last 120 feet of which shows mineral, being in low grade ore, but continually improving as the tunnel goes in. In fact, Wattles says every foot shows a decided improvement in the ore taken from this tunnel. H. C. Wilt has found a rich vein on his claim, and will commence taking out ore as soon as arrangements can be made for reducing it. On his own claim Wattles has a tunnel in 100 feet, and is well satisfied with his prospect. Every man in Cinnabar district is employed, and others who understand the work could find ready employment. There is no snow at the mines and no obstacle to travel in and out. Many new locations have been made, and some of the old claims on which no work has yet been done have been relocated. Lively times are expected in Cinnabar district next summer, as the rush of prospectors will commence as soon as danger from storms is past.

YOLO.

NEW DISCOVERIES.—Yolo *Democrat*, Feb. 14: It has long been known that the range of hills bounding the Sacramento valley on the west contain various kinds of minerals, but for some reason they have never been thoroughly and determinedly prospected in any locality. Coal, iron, tin, quicksilver, silver and gold are known to exist in this range. In one case we know of croppings from a ledge which were assayed and found to yield gold to the amount of \$30 per ton. The other day, however, a new mine was discovered a few miles above Dogtown, in Cache Creek canon, which promises good results. Samples of the ore are now in the assayer's hands in San Francisco, and the result is looked for with intense interest. Pure quicksilver was run out of the specimens obtained, and lead was also melted out with a blow-pipe.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill *News*, February 18: Daily yield, 460 tons of ore. The ore breasts on the 1,300, 1,400 and 1,500-ft. levels are all yielding splendidly and look more promising than ever. No new developments have been made during the past week, with the exception of the continuation of east cross-cut No. 2, on the 1,500-ft. level, the face of which is still in the richest possible character of ore. The mine is showing richer and better the more it is developed, and there is simply no estimating its immense wealth.

ORHR.—The ore stopes on the 1,366-ft. level are both looking and yielding well. The east and west ore stopes on the 1,465-ft. level are also yielding the usual amount of good ore. The east cross-cut on the 1,366-ft level on the California line, is passing through very favorable ground containing numerous stringers and streaks of fine ore. The east cross-cut on the California line, on the 1,465-ft level is also passing through a very changeable and favorable character of ground. The bottom of the north winze on the 1,465-ft level has encountered a new and heavy body of ore dipping strongly to the east, which seems to have turned the course of the stratum of ore passed through a few feet higher up, although the same character of ore still shows under the sills on the east side of the winze. A new station for the head of the main incline, 50 ft below the 1,465-ft level is being opened, the work on which is making good progress. A new station is being opened at the 1,600-ft level, from which point a drift is being run to connect with the new incline. This drift already shows some fine indications of ore.

CALIFORNIA.—The cross-cut near the center of the mine, on the 1,400-ft level is still continued to the eastward, the face in good ore. On the 1,500-ft level the face of both cross-cuts Nos. 1 and 2 are in the richest character of ore, while that of cross-cut No. 3 is in low grade ore, and is daily expected to reach the rich east ore body already developed in the drifts further south. The drift on the 1,550-ft level continues to the north and eastward, the face in the same rich character of ore heretofore described. This drift has now reached a point under cross-cut No. 2 on the 1,500-ft level. Another cross-cut, No. 4, has been started on the 1,500-ft level; also a drift north and east from the main north drift to again connect with the east cross-cut in the ore vein on the Ophir line, running parallel with the ore vein, and from which it will be much easier cross-cutting and prospecting the northern portion of the mine, besides greatly benefiting the air circulation. Sinking the C & C shaft is making excellent progress, the rock in the bottom blasting out finely.

GEORGIA.—The new three-compartment work-

ing shaft is being put down at an active rate. It is very eligibly located, south of the Rock Island shaft, and considerable farther east. They propose erecting hoisting works of the best and most effective character. The shaft will intersect the vein at a depth of about 1,600 ft, but at the depth of 500 ft they will drift to the vein in order to open and work it at that point.

BEACON.—Sinking the main incline is making steady progress. The main north drift on the 1,500-ft level is still driven vigorously ahead, without change of interest to report. The south, middle and north winzes from the 1,400-ft level are all making a fair rate of progress in sinking, the bottom of all still being in good ore. The new air shaft is progressing finely, and will now soon be completed.

GOULD & CURRY.—Enlarging the main shaft below the seventh station level, so as to give three compartments for hoisting, and one for pumping, is making good headway.

SIERRA NEVADA.—Sinking the new shaft is making good progress. The flow of water at the bottom of the shaft has been quite strong for several days past, but is again gradually decreasing. The old Apple shaft is cleaned out and the sinking has been resumed.

YELLOW JACKET.—A new station is being opened at a point in the main incline, 103 ft below the 1,740-ft level. The east cross-cut on the 1,740-ft level is in 315 ft.

SAVAGE.—The 2,200-ft station is about completed, and a drift started to the southward to connect with the north drift from the bottom of the south winze below the 2,000-ft level. Sinking the main incline is making steady progress. The foundation for the new incline machinery is nearly completed.

LADY BRYAN.—Cross-cut No. 3 from the south drift on the 80-ft level has penetrated a fine body of ore a distance of 25 ft. The ore gives an average assay value of about \$63 per ton, and is as yet of an unknown extent. The pump is being lowered to the 380-ft level, at which point a new drift will be started in a very few days to cut and prospect the ore vein.

BULLION.—As soon as a point 100 ft north of the Exchequer line is reached a cross-cut east will be started to determine the character of the ore vein. The prospects of an ore development in the south drift on the 800-ft level continues to improve almost daily.

ORIGINAL GOLD HILL.—Cross-cut No. 2, from the north drift, is completed, showing the ledge to be 60 ft wide, with considerable good ore in it.

MEXICAN.—A cross-cut east has been started from the main north drift on the 1465-ft. level, the face of which is in a very favorable formation for good ore developments, notwithstanding which it is expected that the drift will have a considerable distance yet to run to reach the rich ore body found on the east side of the drift further south.

LEO.—There has been a marked improvement in the character of the ledge material penetrated during the past few days. The ledge is about five feet in width, and carries some fine ore.

CALDONIA.—A new ore and waste chute is being put in at the 1000-ft. level, and a considerable amount of repairing is being done to a portion of the mill shaft.

ROCK ISLAND.—Sinking the shaft for the purpose of opening a new level, is making excellent progress.

CHOLLAR-POTOSI.—The old incline has been cleaned out to the bottom, all the timbers being perfectly sound and the shaft in excellent working condition. The prospects are much more favorable than heretofore for a consolidation of the ore vein on this level and the finding of a continuation of the rich ore body worked on the levels above.

HALE & NORCROSS.—Three drifts are being run at the 2100-ft. level—one north, one south and one west. All of the drifts are in vein matter, and none of them have yet developed any valuable ore bodies. Daily yield of ore from the old stopes above the seventh station level, 40 tons.

DAYTON.—The 400-ft. station has been reached, a station set, put in, and the shaft again continued downward.

WELLS FARGO.—New shaft 140 ft deep. It has passed through the hard country rock, and the bottom is in vein matter and quartz. Water does not trouble.

CROWN POINT.—Sinking the main incline is progressing finely. It is now down to the 1700-ft level. The main east drift on the 1600-ft level is still driven vigorously ahead without change of interest to report. The ore breasts on the 1400 foot level are yielding the usual amount of good ore. Daily yield 400 tons of ore.

WOODVILLE.—Sinking the new shaft is making steady progress. The recently discovered ore body in the north drift on the 300-foot level continues to improve as the development progresses. The width and extent of this ore body is as yet entirely unknown. The mill is kept steadily running on ore from the mine.

SILVER HILL.—The face of the main south drift on the third level is still in fine quartz, carrying some fair grade ore.

IMPERIAL-EMPIRE.—Sinking the main incline is making splendid progress considering the great depth reached. The main south drift, on the 2000-ft level, is still driven vigorously ahead.

JULIA.—The main south drift on the 1000-ft level is advancing steadily along the west wall of the ore vein in a more and more encouraging character of vein material.

BALTIMORE.—The erection of the new pumping machinery is making slow though steady progress.

Arizona.

MINING ITEMS.—Arizona *Citizen*, Feb. 13: L. W. Carr and John W. Hopkins have bought 750 feet in the Ostrich gold mine, and are determined to have a stamp mill on it soon, and are now examining some machinery for that purpose. The main shaft is now down over forty feet, and a ledge of paying quartz eight to ten feet is developed. Both walls of the vein are perfect, and every pound of the ore prospects well in free gold—much of it away up in the hundreds per ton.

Lee & Scott have just let a contract to sink the main shaft on their Negrilla mine fifty feet deeper, and it is now 120 feet deep. This is already demonstrated to be a very rich silver vein, and ore shipped to San Francisco was there worked at a profit to the shippers. The mine is only about twelve miles west of Tucson.

D. A. Bennett left early in the week for the Patagonia country, where himself and Mr. E. N. Fish are engaged in what promises to be very extensive mining operations. They are sinking and find the prospects better than expected. A shaft of 100 feet is down on the San Jose, and of 250 feet on the Santa Maria. They have about 25 men at work, and Mr. Padres employs 45 men in smelting ore obtained from the San Jose and Santa Maria. Mr. Bennett informed us that they expected to commence smelting inside of two months, but desired to make certain developments first, which they are doing vigorously.

Colorado.

CLEAR CREEK COUNTY.—Colorado *Miner*, Feb. 13: The Clark mining company's ground on the Terrible is yielding to the lessees who are working it ore that fully sustains the royal character of this great mine.

JOHN COLLOM writes to the *Miner* as follows: I am happy to inform the miners of Georgetown that the arrangements are now made for building the Colloim concentration works in Georgetown, and that we intend to commence the erection as soon as the cold weather is over. The capacity of the works will be one hundred tons a day, so that we shall be prepared to buy and concentrate all the low grade ores that the mines of Georgetown will produce.

DENVER SMELTING WORKS.—The Denver smelting works, at Swansea (Denver Junction), have been purchased by Mr. William Lawson, a gentleman of abundant means from England. He will immediately send to England for a gentleman to come here and take charge of the works. Possessing as he does plenty of capital necessary to carry them on, this purchase appears to be particularly opportune and gratifying.

Idaho.

BOISE COUNTY ITEMS.—Cor. Silver City *Avan-lanch* Feb. 15: Except prospecting in quartz, little is being done here at present.

Some of the boys have struck a rich streak in a ledge belonging to J. G. Hnghs & Co. A large portion of it pays \$3 to the psn, and the remainder is over an average milling ore in a 4-foot vein.

Nothing but prospecting is required to prove our range of mountains second to no other camp in the Territory. But situated as we are—nearly all of us poor—we cannot, without the aid of capital, open our mines successfully. Our ledges, barred as they are with gold, open out to the magic touch of golden keys.

It is reported that operations will be resumed the ensuing summer on the Mammoth ledge, at Summit Flat. In times past considerable money was taken from the mine and those interested retired with a "home stake." Being cautious men, they were afraid to invest what they had already made by putting it into the ground again, and so left it; now, however, they have either made some arrangement, or gave gained a little courage, and are about to have another slap at it, probably with the intention of selling. Mammoth ore never milled less than \$50 per ton, and is very hard.

The owners of the different mines are confident of being able to work out their own salvation, without the aid of outside resources, and some there are who would not sell under any consideration.

Oregon.

MINING ITEMS.—Oregon *Independent*, Feb. 17: The late pleasant weather has started prospecting in a way that will soon determine the actual worth of the late numerous discoveries reported by us, as well as extend the field already gone over. Earnest work is begun on nearly or quite all the ledges heretofore spoken of and prospecting is being done at this time in localities so remote that we are able to obtain only occasional reports.

The "Hodges" cinnabar lead. The last most extensive discovery of cinnabar was made public about a week ago. It was discovered near a place known as "The Meadows," on Evans creek, about 30 miles northeast of here, by a man named Daniel Hodges, who had been prospecting in that region for several weeks, living at times on bread and water; but so sanguine was he of success, notwithstanding the adverse counsel, and even ridicule of acquaintances, that he persevered against all obstacles until finally rewarded with the discovery of what promises to be the most valuable lead of that ore yet found. After locating what ground he desired he notified his friends, and soon parties from here were on their way to secure claims. Thus far ten claims of 1,500 feet each have been recorded.

Irrigating and Other Canals.

A State System of Canals for the Development of the "Field," the "Forest," and the "Mine,"—Its Immense Benefit to California—How the City and the State Would be Enriched.—By a Distinguished Engineer.

What the New York State Canals Have Cost.

The navigable canals constructed by New York State since 1817, aggregate a total length of 907 miles.

The cost of construction to 1874 is.....	\$64,710,832
The cost of maintenance, repairs and collection.....	24,377,108
Total cost of construction and maintenance, etc.....	\$89,087,940
Receipts from tolls were.....	97,525,056
The actual cost, including the interest thereon, is.....	\$64,710,832
Total interest on same.....	93,736,554
Total cost maintenance, repairs, and collection.....	24,377,108
Total interest on same.....	27,258,595

Total cost from commencement to completion.....	\$210,093,489
Aggregate receipts from tolls, with interest.....	202,619,510

Present cost to State of the entire canal system..... \$7,473,569

Number and Tonnage Capacity of the Boats.

There are 6,511 boats, having an aggregate of 971,395, the average tonnage of the boats being 160 tons. The age of the present boats is ten years, and the total number of navigable days in ten years is 2,268 days: (In California there would be 3,650 days.)

Cost of Transportation.

Cost of boats complete.....	\$ 5,000
Interest on same for ten years.....	3,500
Repairs, with interest on same.....	2,061
Expense of crew, \$185 per month.....	15,555
Expense of towing, 35 cts. per mile, 79,526 miles.....	30,334

Total for 2,268 days..... \$57,451

Total for one day..... \$25.33

Total per mile..... 72

Average burthen of boats, up and down tonnage..... 155

Actual cost, exclusive of tolls, per ton per mile..... 4.61 mile

The average current charges upon all classes of freight upon the canals, per ton per mile..... 5.55 "

Leaving a profit of..... 1.05 "

Average receipts from tolls..... 4.38 "

Total cost per ton per mile (5.55-4.38)..... 10.04 "

Results.

During the 10 years ending 1864, the New York State canals moved 8,175,803,065 tons, average receipts from which were 0.91 cents per ton per mile, as against 2,132,073,612 tons moved by the New York Central Railway, the average receipts of which were \$2.60 per ton per mile; and 2,587,274,914 tons moved by the Erie Railway, the receipts from which were \$2.22 per ton per mile. The average of both railways being 2½ times the cost upon the canals.

In 1867 the business of the canals was as much as the aggregate of the three years (1865-1867) of the New York Central Railway.

It is calculated that the revenues of the canal will, with the tolls at the present low rates, extinguish the debt yet to be redeemed in the cost of these works in less than fourteen years, and that a tax of seven and a half mills upon the dollar of assessed property would discharge it in a single year.

The State of New York has, since 1825, unaided, and without embarrassment, or an undue extension of its credit, and when its resources and wealth were undeveloped, expended these many millions in the construction, maintenance, and working of the canals. Notwithstanding that the canals are closed annually for about five months, by Jack Frost, they carried for the ten years previous to 1870, about 24 per cent. more freight than the New York Central and Erie railways together, which were working all the time. It would be impossible for the State to prosper without this system of canals, and the railways cannot supplant them and absorb all the internal carrying trade of the country. The "Field," the "Forest," and the "Mine" yield products which are bulky and of small value compared with their weights, and they do not require to be transported at 15 to 20 miles an hour. At a speed of 2½ to 3 miles an hour such goods can be carried on canals at such low rates that no railroad could compete with them.

Both are, however, necessary for the prosperity of the State, and both are of mutual advantage. The railroads are necessary for passengers and for perishable goods, for which the canals are not available. Notwithstanding the closure of the Erie Canal by frost for so many months, it has moved annually 6,000,000 of tons, which is more than the full work of six double-track first-class railways, and yet it is only 70 feet wide on the surface, and has a depth of seven feet of water. What would Chicago, Milwaukee, Cleveland, Rochester, Buffalo, Syracuse or Utica have done, or have been without the Erie Canal?

This canal transports, in eight months, twice the whole foreign tonnage of the port of New York. Governor Morris, the projector of the Erie Canal, in writing to Mr. Parish in England in January, 1801, showed his wonderful foresight. He says: "Shall I lead your astonishment up to the verge of incredulity? I will. Know you that one-tenth of the expense borne by Britain in the last campaign would enable ships to sail from London, through Hudson's river, into Lake Erie. As yet, my friend, we only crawl along the outer shell of our country.

The interior excels the part we inhabit in soil, in climate, in everything. The proudest empire in Europe is but a bubble compared to what America will be in the course of two centuries, perhaps in one."

This being the showing of the New York State canals, let us now see what the State of California might do in the same direction, combining irrigation with cheap transportation. We have the New York State canals as a precedent of financial success, notwithstanding the many mistakes made and the political influences which have increased the cost of the same.

System of Canals for the Plains of California.

The San Joaquin and Sacramento together form the great valley of California. This is the great backbone in the future prosperity of the State, and already the source of an immense business to the city of San Francisco. The geographical features of the San Joaquin valley, on the west side, must always prevent the rain fall from being sufficient to mature the grain crops, and to afford permanent pasturage. Irrigation is therefore an acknowledged necessity, and until the lands can be watered by artificial means, this vast area of rich and easily cultivated land must remain more or less unproductive and uncultivated. A main canal connecting Kern and Buena Vista lakes with Tulare lake, and Tulare lake with Suisun bay, will open out the entire western slope of the valley and bring San Francisco in direct communication with the extreme southern portion of the valley.

Again, a main canal from Suisun bay, along the western slope of the Sacramento valley to the junction of the Sacramento and Pit rivers, and the improvement of Pit river to its connection with Goose lake, and the connection of Goose lake with Klamath lake, and Klamath lake with the Columbia river along the Des Chutes valley for purposes of navigation and irrigation, is a project deserving the attention of the State and of action by the next Legislature.

Some Estimates.

The following table of the cost of transport per mile is deserving of careful consideration:

	Mile.
Ocean, long voyage, per ton per mile.....	1
Ocean, short voyage, per ton per mile.....	2 to 4
Lake, long voyage, per ton per mile.....	2
Lake, short voyage, per ton per mile.....	3 to 4
Rivers—Hudson, and of similar character.....	2.5
Rivers—St. Lawrence and Mississippi.....	3
Rivers—Tributaries of the Mississippi.....	5 to 10
Canals—Erie.....	4
Canals—Ordinary size.....	5
Canals—Ordinary size, great lockage.....	5 to 8
Railroads—Transporting coal.....	6 to 10
Railroads—Not for coal; favorable grades.....	12.5
Railroads—Not for coal; steep grades.....	15 to 15

The cost of movement on a canal depends upon the relative sectional areas of the boat and of the canal; upon the actual size of the two, and upon the elevation to be overcome. The increased cost of transportation on the New York canal, due to the suspension of navigation from frost, is an item that will not exist in the great valley of California system of canals. The actual cost (not charge) of transit by steam on the Forth and Clyde Canal, including everything (not tolls), is 1-20 cent. This canal is closed for some time by frost.

If the main canals cost \$15,000 per mile, and carried a million tons, the tolls would be 1-40 cent to cover 7 per cent. for interest; and taking the cost of transit at the same rate, the total cost would be 1-20 cent against 1 to 2 cents, the total cost by rail. But in the case of canals along the western slope of the San Joaquin and Sacramento valleys, irrigation would be combined with transportation, and the sales of water for irrigation and mill power (if the canals are owned by the State), would enable the tolls for transportation to be very low, and consequently the State of California could possess a system of canals that could be operated to far greater advantage in the interests of the public than the New York canals have been. If the country required speed, of course it could have it, by a greater expenditure on the protection of the canal-banks, and by an increase in the rate of tolls. The Hudson and the Clyde are worked at 15 to 18 miles an hour, and there is nothing to prevent a higher speed, except the expense of works of protection. But the question is, how can we carry a million or two tons a year on a certain line at 1.10 to 1.20 cent per ton per mile, and this can only be done by large navigable canals.

Advantages of Canals Over Railways.

Canals protect the country from drought, and railways do not.

Canals carry at rates which make even grain at one cent a pound remunerative, although grown 300 miles from tide-water; this railways cannot do. Canals increase the value of lands several hundred fold where the rain-fall is always deficient, and induce immigration and cultivation on such lands. Canals in such districts of deficient rain-fall, or where the rains occur during only a few months of the year, by encouraging cultivation and immigration, also develop the railway system, and make the same a necessity for the transit of passengers and of perishable goods.

Advantages to the State.

By the early completion of such large canals for the purposes of irrigation and navigation the State will increase the taxable property of the country, and so reduce the pressure on the present population. Merchants and farmers would not then be discouraged at the present low price of wheat, because if the State canals could convey at 0.5 cent per ton per mile, the

average cost of moving wheat a distance of 200 miles, would be one dollar a ton. The advantage in having such works carried out by the State consists, moreover, in the fact that the credit of the State enables it to obtain loans at a lower rate of interest than private companies can, and there is therefore, no necessity for burdening the country with taxes to pay for works of this character, which will much more than pay for themselves.

No sensible or well-read man can doubt the financial excess of well laid out and carefully-constructed canals for irrigation and transportation. The New York canals are a proof of the latter item, and the canals in Europe and India are overwhelming proofs of the former.

"Popular Errors."

Many persons argue that the time is not yet ripe for such a system of canals; that the country is too sparsely inhabited. Such persons forget the simplest principles of the traffic question, the first point of which is that communications make traffic. Afford the communication and population will flow in, and traffic must ensue. If the drought of 1864 and of 1871 was so terrible in these plains of California, what would not similar droughts be with the present population therein? If the farmers and cattle and sheep owners can be secured from their present misery and anxiety, whenever signs of similar drought are present, will it not tend to induce a better and more permanent settlement of these great interior plains? The loss of thousands of sheep and cattle from starvation is a direct loss to the entire community. A State charge of even five cents a head a year on all the cattle and sheep of these plains, for the purpose of developing a system of irrigation and cheap transportation, would be a boon to the stock men compared with the present risks they now run from periodical droughts.

What Irrigation Canals Would Do.

A general system of irrigation and canals for transportation by the State would do more than anything else to break up the present evils arising from large land-ownership.

It would make the lands too valuable to be held, as now, for stock-raising, and the consequent increased assessments from \$2 to even \$6 would force the large land-owners to divide the lands into small farms. At the same time there would be an immense increase in the number of sheep, cattle hogs and horses raised on the same land. Although the State's credit and sovereignty is necessary to raise the loans and to enforce the proper working of the canal system, yet in some way or other the private land-owners whose estates are improved should be made liable by law to pay for all that is done to improve the land. If the State were to make advances for works of permanent value to the reproductive powers of any section belonging to private parties, such advances should be repaid by installments from rents and sales of land at such rates as shall extinguish the debt in a reasonable number of years; and if the landlord should be unable to repay such advances, the State should have the power to foreclose its mortgage on the land.

Take the case of the west side of the San Joaquin valley, from Tulare lake to tide-water, at say Martinez. Here we have about 500,000 acres of land, well adapted, by the quality of the soil and the evenness of its surface, for irrigation. The irrigation of this large area is chiefly dependent upon the waters of King's river and Tulare lake. The settled portion, in farms of reasonable size, is in the lower part of the valley, and there are not much over 10,000 acres, out of the 500,000 acres, in the hands of small farmers. These unfortunate parties are therefore at the mercy of the large land-owners who own the lands between them and the necessary water-supply.

Now, if the State would amend the Constitution at the next general election, so as to enable it to undertake the canal work, these small farmers would in three years have a system of irrigation and a canal available for transportation. The large land-owners would also find it to their advantage to have the State system of irrigation laid out on one or two sections in width along the line of the main canal; and unless they were unusually short-sighted in regard to their own interests, they would readily support the Legislature in any such enterprise. These 500,000 acres could then, in the course of twenty years, be divided into a large number of farms, capable of supporting a population of 100,000 where now there is less than 5,000.

The New York State, in Article 7 of the Constitution, provided for the construction, maintenance, and regulation of the canal system; why cannot California do the same and combine irrigation with cheap transportation? The natural facilities are immense. Nature, in the provision of Tulare lake, the wonderful evenness of the country, the constant supply of water in the snows of the Sierra Nevada, and in the climate, has done nine-tenths of the work. The State alone can have the power to control the necessary system of irrigation and drainage, so necessary in connection therewith; and there are so many millions of acres in need of irrigation and reclamation, and which require to be dealt with on a complete system that it is impossible for private enterprise to work it out. Whether the people irrigate or not, they have the immense benefits of navigation, drainage, timber, cheap food and forage.

Benefit to Mines—Great Possibilities.

The mining districts will be likewise benefited in the increased cheapness of bacon,

beans, etc., which are now imported from the East.

No country in the world could furnish more pork and bacon, cheese, honey and flour, than the San Joaquin valley, if the advantages of irrigation were available. The portions of the State which are not dependent on irrigation need not hesitate to support the action of the State Legislature in the direction of canals, because they must be benefited indirectly if not directly. The lumber business of Mendocino, for instance, will be largely increased, in the supply of fencing and building lumber. The mining counties will obtain their bacon and beans, etc., at a very considerable reduction on present rates. San Francisco will be brought in direct water communication with this vast back country, and, therefore, cannot fail to reap largely from such facilities. The State could make contracts with private companies to construct the canals, and save in that way considerable outlay and trouble. But it should exercise a constant control over the distribution of the water and in the proper adjustment of the canals and system of ditches. The general question of irrigation by the State is one that well deserves the attention of every Californian.—*Bulletin.*

DUBIOUS BUT WORTH EXAMINATION.—SPONTANEOUS COMBUSTION.—Somebody has stated that when oxide of iron is placed in contact with timber, excluded from the atmosphere, and sided by a slight increased atmosphere, the oxide parts with its oxygen, and is converted into very fine divided particles of metallic iron, having such an affinity for oxygen that, when afterwards exposed to the action of the atmosphere from any cause, the gas is absorbed so rapidly that these particles become rapidly red hot, and if in sufficient quantity will produce a temperature far beyond the ignitable point of any timber. Whenever, therefore, iron pipes are employed for the circulation of hot water, air or steam, and when in close contact with timber are allowed to become rusty, it is only necessary to suppose that under these circumstances the finely divided particles of metallic iron becomes exposed to the action of the atmosphere, in order to account for many of the fires which take place at the commencement of the winter season.

In the California mine, the face of the east cross-cut, on the 1,400-ft. level, is in one of the richest possible character, proving beyond a doubt, the extension of the ore body, from the 1,500-ft. level up to and above the 1,400. This is a development of great importance, as it establishes the unbroken continuation of the great ore body from the 1,400-ft. level down to the 1,550-ft. level, where the quality of the ore is unsurpassed in richness, and its breadth and extent as yet literally unknown.

SOLD.—The Wetherell mine, situated in Hutch's canyon, in the White mountain range, in the extreme western portion of Esmeralda county, Nevada, has recently been sold to a San Francisco company. The exact amount paid for the property is not known, but it is said to be about \$65,000. The site includes the mine, mill, wood-ranch, mill site, water privileges, pack animals, and all the paraphernalia belonging to the mine and reduction works.

At Mrk's mill, Mono county, the old reverberatory furnaces have been torn out and a White furnace is being put in. When completed the mill will have a capacity of from ten to thirteen tons per day, and there are about 1,000 tons of roasted ore on the dump ready for work.

The bevel-screw, or ship timber saw, which the Ship-building Association of Vallejo has ordered by telegraph from the East, will be the only one of the kind on the Pacific coast, excepting at the Navy Yard. It is a most valuable invention, and will do the work of over twenty men.

Mr. BULGER, engineer of the United States Mint in this city, has recovered from the injury he sustained by a piece of iron falling on his foot recently, and is now at his post again. He has been confined to his room for nearly two months.

THE TIMBERS used at the Petaluma mine, Eureka, are from the Ruby range of mountains, and are said to be superior to the Sierra Nevada growth of pine, being more tough and less brittle.

A LARGE amount of merchandise, quicksilver, etc. has arrived at Eureka, Nev., on its way to Revelle District. It is expected that a mill will be running there shortly.

O. M. EVANS shipped last week, from Nev., 75 tons of antimony ore to this city. It is from Evan's mine near Unionville. Fifty-two more tons will be shipped this week.

A TWELVE-foot vein of antimony has been discovered about twenty miles from Cimarron, New Mexico, on Red river.

The prospects are excellent for quite a town springing up at the Galice Creek mines this summer.

THERE are forty-three quartz mills in Montana, containing 466 stamps.

A LARGE quantity of ore from Castle Dome, Arizona, is now on the way to this city, by sea.

Good Health.

Diphtheria—Symptoms, Treatment and Prevention.

The following information, from a no less authoritative source than the Report of the Sanitary Committee of New York, and which embodies deductions from the investigations of the latest and most competent medical authorities, ought to be generally diffused:

Mode of attack.—Diphtheria is caused by the inoculation of the air-passages with the diphtheritic poison, which from this point infects the whole system; the local inflammation is attended with the formation of membrane (exudation); the fever and general symptoms are the result of this local infection.

How it Spreads.—Diphtheria is therefore a contagious disease (not, perhaps, as marked as scarlet fever), induced by contact with objects infected. It may be diffused by the exhalations of the sick and the air surrounding them; or directly by the exudation, as in the act of kissing, coughing, spitting, sneezing; or by the infected articles used, as towels, napkins, handkerchiefs, etc. The poison clings with great tenacity to certain places, rooms, houses, where it may occasion cases after the lapse of months.

Symptoms.—In ordinary attacks the poison begins to act the moment it lodges upon the tissues; but, like a vaccination, at first causes but slight sensible effects. In from two to five days there is marked prostration, dryness of throat, and pricking pain in swallowing; the throat becomes red, and patches of white exudation appear, and the glands of the neck swell. In mild cases these symptoms subside on the third or fourth day from the appearance; if more severe, these symptoms may be prolonged; if unfavorable, the fever increases, the local inflammation spreads, and exhaustion rapidly follows.

Predisposing Conditions.

The Person.—Diphtheria attacks by preference children between the ages of one and ten years, the greatest mortality being in the second, third and fourth years; children of feeble constitutions, and those weakened by previous sickness, and those suffering from catarrh, croup, and other forms of throat affections.

Social Relations.—All classes are liable to diphtheria where it is prevailing, but those suffer most severely who live on low, wet grounds; in houses with imperfect drains, or surrounded by offensive matters, as privies, decaying animal or vegetable refuse; in damp rooms, as cellars; in overcrowded and unventilated apartments.

Seasons.—Diphtheria is not affected by either heat or cold, drought or rain.

Precautions—The Dwelling or Apartment.—Cleanliness in and around the dwelling, and pure air in living and sleeping rooms, are of the utmost importance wherever any contagious disease is prevailing, as cleanliness tends both to prevent and mitigate it. Every kind and source of filth in and through the house should be thoroughly removed; cellars and foul areas should be cleaned and disinfected; drains should be put in thorough repair; dirty walls and ceiling should be lime-washed, and fever occupied room should be thoroughly ventilated. Apartments which have been occupied by persons sick with diphtheria should be cleansed with disinfectants, ceilings lime-washed and wood-work painted; the carpets, bed-clothes, upholstered furniture, etc., exposed many days to fresh air and the sunlight (all articles which may be boiled or subjected to high degrees of heat should be thus disinfected). Such rooms should be exposed to currents of fresh air for at least one week before reoccupation.

Well Children.—While diphtheria is prevailing, no child should be allowed to kiss strange children nor those suffering from sore throat (the disgusting custom of compelling children to kiss every visitor is a well contrived method of propagating other grave diseases than diphtheria), nor should it sleep with, or be confined to rooms occupied by, or use articles, as toys taken in the month, handkerchiefs, etc., belonging to children having sore throat, croup, or catarrh. If the weather is cold the child should be warmly clothed with flannels.

When Diphtheria is in the House or in the Family.—The well children should be scrupulously kept apart from the sick, in dry, well-ventilated rooms, and every possible source of infection, through the air, by personal contact with the sick, and by articles used about them or in their rooms, should be rigidly guarded. Every attack of sore throat, croup and catarrh, should be at once attended to. The feeble should have invigorating food and treatment.

Sick Children.—The sick should be rigidly isolated in well-aired (the air being entirely changed at least hourly) unlighted rooms, the outflow of air being as far as possible through the external windows by depressing the upper and elevating the lower sash, or a chimney heated by fire in an open fire-place. All discharges from the mouth and nose should be received into vessels containing disinfectants, or upon cloths which are immediately burned, or, if not burned, thoroughly boiled, or placed under a disinfecting fluid.

While scarlatina, small-pox and enteric fever are scouring numerous cities in England, diphtheria is now prevailing in about half the cities with which this bureau holds correspondence in the United States, and it is more fatal in numerous interior towns and cities than it is

in this city, where its increase seems to be stayed. No other infectious malady more imperatively demands the best resources of medical and sanitary knowledge to limit its prevalence and save life. Sanitary precautions have supreme importance in this disease.

Do not Eat Raw Eggs.

One of the most common prejudices of housewives and mothers is that hard eggs are difficult to digest, especially the white, and that the less they are boiled the better they are for weak and dyspeptic stomachs. A medical journal of good authority, however, reverses the case and asserts that there is more danger of raw and soft white of an egg passing through the digestive apparatus without being really digested than when thoroughly boiled and hard; in fact, that a hard boiled egg constitutes a most excellent food for dyspeptics, as experience is proving. A writer in the *Medical Journal* says: "We have seen dyspeptics who suffered untold torments with almost every kind of food. No liquid could be taken without suffering; bread became a burning acid; meat and milk were solid and liquid fires. We have seen these same sufferers trying to avoid food and drink, and even going to the enema syringe for sustenance. And we have seen their torments pass away and their hunger relieved by living upon the white of eggs which had been boiled in bubbling water for thirty minutes. At the end of a week we have given the hard yolk of the egg with the white, and upon this diet alone, without fluid of any kind, we have seen them begin to gain flesh and strength, and refreshing sleep. After weeks of this treatment they have been able, with care, to begin upon other food." And all this, the writer adds, without taking medicine. He says, what we also have always maintained, that hard-boiled eggs are not half so bad as half-boiled ones, and ten times as easy to digest as raw eggs; and we have no doubt that an animal may be starved to death by eating only raw white of egg, for the same reason that dogs have been starved by eating gelatin alone. Only toothless babies can digest soft food, such as milk.

Unaired Rooms.—A writer in the *Country Gentleman* says: "I pass some houses in every town whose windows might as well be sealed in with the walls, for any purpose that they have but to let in light. They are never opened, summer or winter. In winter it is cold; in the summer the flies stray in, or, if they are netted, the dust sifts through the nets. Now, I can tell a person who inhabits such chambers when I see him in the street—there is such a smell about his clothing I always wish for a sniff of cologne or hartshorn, or burnt leather or something of the sort, 'to take the taste out.' A house that is never aired has every nook and corner filled with stale odors of cooked meats, boiled vegetables, especially cabbages and onions, which, as the weeks go by, literally reek in their hiding places. The very garments of their children tell the same story of uncleanness. It is bad to have unwashed clothes, but there may be an excuse for it. But what excuse can there be for unaired ones, when air is so cheap and free? There is death in such unaired chambers. Better a swarm of flies or a cloud of dust; better frost and snow in a room than these intolerable smells. The first thing in the morning, when you are ready to go down stairs, throw open your windows, take apart the clothing of your beds, and let the air blow through it as hard as it will. There is health in such a policy."

WARTS.—Dr. Guttoseit recommends rubbing warts, night and morning, with a moistened piece of muriate of ammonia. They soften and dwindle away, leaving no such white mark as follows their dispersion with lunar caustic.

Useful Information.

COLORS IN CARPETS AND UPHOLSTERY.—Put a good amount of color on ceiling, not, however, making it so dark as to bring it too close to the eye. The carpets must be either lighter or darker than the walls. This is following out the artist's rule, to make either background or foreground run into the figure. If this is not done in painting, a woman in white satin, for instance, against a dark floor and dark walls, will look like a cut-out figure stuck on, and the same sort of a result would occur in rooms. As in ordinary life, dresses are dark in color, where a light wall tone has been recommended, the carpet will have to be darker than the walls. Not too vivid in color, however, and, of course, no flowers, ferns, birds' nests, and such like fearful things. Furniture and hangings should not be too much alike in color; have, say, the carpet one tone, the coverings of furniture another, and the curtains and other hangings a third. Have summer and winter hangings and furniture coverings; those for the former light and cheerful, the others with more warmth, and suggestive of comfort and home life. A table-cloth, occasionally a chair, or a rug, may supply a bit of effective contrast with prevailing hues of hangings, etc., and a spot of vivid color in a vase or some small hanging will complete the formal decoration of the room. —*Brit. Arch. Asso. paper.*

Rock or swamp maple is a better step for a turbine than either *lignum vitæ* or elm. Cast iron is useless. So says the *Scientific American*.

The Common Hammer.

Few people, in witnessing the use of a hammer, or in using one themselves, ever think of it as an engine giving out tons of force, concentrating and applying power by functions which, if performed by other mechanism, would involve trains of gearing, levers, or screws; and that such mechanism, if employed instead of hammers, must lack that important function of applying force in any direction that the will may direct.

A simple band hammer is, in the abstract, one of the most intricate of mechanical agents, that is, its action is more difficult to analyze than that of many complex machines involving trains of mechanism; but our familiarity with hammers makes us overlook this fact, and the hammer has even been denied a place among those mechanical contrivances to which there has been applied the mistaken name of mechanical powers.

Let the reader compare a hammer with a wheel and axle, inclined plane, screw or lever, as an agent for concentrating and applying power, noting the principles of its action first, and then considering its universal use, and he will conclude that if there is a mechanical device that comprehends distinct principles, that device is the common hammer; it seems, indeed, to be one of those things provided to meet a human necessity, and without which mechanical industry could not be carried on. In the manipulation of nearly every kind of material, the hammer is continually necessary in order to exert a force beyond what the hands may do, unaided by mechanism to multiply their force. A carpenter in driving a spike requires a force of from one to two tons, a blacksmith requires a force of from five pounds to five tons to meet the requirements of his work, a stone mason applies a force of from one hundred to one thousand pounds in driving the edge of his tools; chipping, calking, in fact nearly all mechanical operations consist more or less in blows, and blows are but the application of an accumulated force expended throughout a limited distance.

Considered as a mechanical agent, the hammer concentrates the power of the arms and applies it in a manner that meets the requirements of the work. If great force is needed, a long swing and slow blows accomplish tons; if but little force is required, a short swing and rapid blows will serve, the degree of force being not only continuously at control, but the direction at which it is applied also. Other mechanism, if used instead of hammers to perform the same duty, would from its nature require to be a complicated machine, and act but in one direction or in one plane. —*Journal of Iron.*

WRITE PLAIN ENGLISH.—A very common mistake with writers on scientific and mechanical topics for popular perusal, is the indulgence in technical terms and algebraic formulas to an unnecessary extent. Such writings often fall far short of comprehension by the readers to whom they are addressed. It does not need that the scientific writer should "etooop to conquer," or simplify his lucubrations to a childish degree, but good plain English, which persists in calling a spade a spade, should be used in all cases, leaving mere jargon of nomenclature to the society meeting, or the scientific quarterly. It is no disparagement to working mechanics that they do not generally understand these things, since it is sometimes a matter of doubt whether the writers do themselves.

TO BLEACH FLANNEL.—Flannel which has become yellow with use may be bleached by putting it for some days in a solution of hard soap to which strong ammonia has been added. The right proportions are one and a half pounds of hard cut soap, 50 pounds of soft water and two-thirds pound of strong ammonia solution. The same object may be attained in a shorter time by placing the flannel for a quarter of an hour in a weak solution of bisulphite of sodium, to which a little hydrochloric acid has been added.

VAPORIZING IRON.—According to Professor Langley, five thousand tons of iron is vaporized every year by the furnaces in Pittsburgh, passing off through the chimneys, and this remarkable fact he uses as a measure to indicate the amount of the sun's heat. The volatilization of the iron is accomplished by what is a very small quantity of coal compared to all that the Pennsylvania coal fields contain; and yet the whole of the coal estimated to lie within that State would maintain the sun's heat only a small fraction of a second.

WICKS IN KEROSENE LAMPS.—The unsatisfactory light frequently given by kerosene lamps, is often due to impurities which have collected in the wick. The filtering of several quarts of oil through a wick, which stops every particle of dust in it, must necessarily gradually obstruct the pores of the wick—consequently, although a wick may be long enough to last some time, its conducting power may be so impaired that a good light cannot be obtained.

HOPS AND HOP-STALKS.—In Sweden a strong cloth is manufactured from hop-stalks. The stalks are gathered in autumn, and soaked in water during the whole winter. The material is then dried in an oven and woven as flax. The buds of hops can be used as an esculent, and when boiled will do as a substitute for asparagus. The tendrils, when young, may be used in the same way.

Domestic Economy.

Tomatoes for Supper.

Few people know how to prepare uncooked tomatoes in the way adopted in my family, and incomparably better than any mode I have ever tasted. By this mode they are very desirable for supper or breakfast. For a family of half a dozen persons take six eggs, boil four of them hard, dissolve the yolks with vinegar sufficient, add about three teaspoons of mustard, and mash as soon as possible; then add the two remaining eggs (raw), yolk and white, stir well; then add salad oil, to make altogether sauce sufficient to cover the tomatoes well; and plenty of salt and cayenne pepper, and beat thoroughly till it frosts. Skin and cut the tomatoes a full fourth of an inch thick, and pour the sauce over, and you have a dish fit for a president. Though a little troublesome to prepare, yet if once eaten by people who are blessed with palates to enjoy good things, they will be pronounced to be far superior, to any other mode of preparation. For dinner they are best stewed, but they should always be strained before sending to the table. —*Cor. Germantown Telegraph.*

TO BOIL A HAM.—Take a ham weighing about eight or ten pounds, soak it for twelve or twenty-four hours in cold water, then cover it with boiling water, add one pint of vinegar, two or three bay leaves, a little bunch of thyme and parsley (the dried and sifted will do, or even the seeds of parsley may be used if the fresh cannot be procured); boil very slowly two hours and a half, take it out, skim it, remove all the fat, except a layer about half an inch thick; cut off with a sharp knife all the black looking outside, put the ham into your dripping pan, put side uppermost, grate bread crust over it and sprinkle a teaspoonful of powdered sugar over it; put it in the oven for half an hour, until it is a beautiful brown.

Eat cold; cut the nicest portion in slices; the ragged and little odds and ends can be chopped fine and used for sandwiches; or, by adding three eggs to one pint of the chopped ham and frying brown you have a delicious omelet for breakfast or lunch. The bone should be put into the soup kettle. The rind and fat should be rendered and strained for frying potatoes or cutlets. A ham prepared in this way will go twice as far as when cooked and served in the ordinary manner, besides the conviction it gives the housekeeper of being economical, and at the same time placing neat and palatable dishes before her family.

An excellent breakfast dish can be made from the remains of a ham. Take about a pound and a half of the ham, both fat and less, put it into the mortar and pound it. Boil two large slices of bread in a pint of milk, add three boiled and mashed potatoes and one egg. Mix it with the ham, beat up well and bake it a rich brown.

GOOD TARTS.—Pare and core about a dozen nice apples, put them into a saucepan to stew, adding a little water; stir them frequently, and when they are cooked to a pulp, add a pound of currants and enough sugar for sweetening nicely. To this add a teaspoon of rich cream, flavored with vanilla. Line a deep tart dish with puff paste, pour into it the apples and cream, and cover it with another piece of paste of the same thickness and size, and press the edges closely together. Place in the oven and bake to a rich brown. Serve with wine sauce.

POTATO CHOPS.—Boil and mash some nice mealy potatoes, then, with one or two well beaten eggs, make them into a paste, work it well, dust it over with flour and roll out. Take some nice thin neck of mutton or lamb chops, carefully trim off the fat, pepper and salt them on both sides, cut the paste into shape, cover over like a puff, pinch the edges and fry of a light brown; they look better if about an inch of the bone is left visible.

ICING THAT WILL NOT BREAK.—Take one pound of pulverized sugar and the whites of three fresh eggs, well beaten. Mix them well together, and flavor with the juice of one lemon or add a teaspoonful of strong odor vinegar. Pulverize one teaspoonful of wheat or corn starch and add to it. Flour the top of the cake as soon as it is taken from the oven, and put on the icing with a large bladed steel knife into warm water, and then smooth the frosting with it.

TASTE OF PINE.—A pine curbhog to a well or spring which has but a small discharge where it comes in contact with the water, often causes it taste of the wood. If boards so used are soaked in milk of lime, or a solution of potash and soda before being put into the well, there will be no trouble.

SUGARED POP-CORN.—One cup of white sugar, half a cup of water, boil till it taffies, and sprinkle in the pop-corn as much as the pan will hold. If nicely popped this will sugar two quarts of corn. Stir well, so that it does not stick together. The grains ought to be separated.

RAISED WAFFLES.—One pint of sweet milk, one teaspoonful of butter, three eggs, a teaspoonful of thick brewers' yeast, one quart of flour, and another cup of milk, in which dissolve a teaspoonful of soda. Let it all rise until light, and then bake like other waffles. Serve with butter and sugar or maple syrup.

Agricultural Lectures at Berkeley.

Our readers are of course aware that several
 courses of lectures have been delivered at the
 University of California within the past few
 months, on agricultural subjects. A number
 of these lectures have been published in the
 Press for the benefit of those who could not
 attend. The courses already delivered are as
 follows: "On the Analysis of Soils," by Prof.
 Engene Hilgard, of the University of Michi-
 gan; "On the Chemistry of Household Life,"
 by Prof. Hilgard; "On Economic Botany, or
 the Plants which are Useful and Harmful in
 Human Industry," by Prof. C. E. Bessey, of
 the Iowa Agricultural College; "On the Im-
 provements of Varieties in Plants and An-
 imals," by Prof. Bessey. A course of Lectures
 will shortly be given "On Stock Breeding," by
 Prof. W. H. Brewer, Botanist of the California
 Geological Survey and Professor of Agricul-
 ture in the Sheffield Scientific School.

A miscellaneous course on subjects pertaining
 to agriculture will soon be given on the follow-
 ing named subjects: "On Insects Injurious to
 Vegetation," by Henry Edwards, Vice-President
 of the California Academy of Sciences; "On
 Forestry," by Prof. H. N. Bolander, State
 Superintendent of Public Instruction; "On
 Orange Culture," by Dr. Strenzel, of Martinez;
 "On Wheat," by Horace Davis, Esq.; "On Local
 Field Botany," by Dr. W. P. Gibbons, of
 Alameda, and Dr. A. Kellogg, Director of the
 Museum of California Academy of Sciences;
 "On Lower Forms of Vegetable Life," by Dr.
 H. W. Harkness; "On the Encalyptus Tree,"
 by R. E. C. Stearns, Secretary of Regents,
 Berkeley; "On Cotton Culture," by J. W. A.
 Wright, Lecturer of State Grade of California;
 "On the History of California Agriculture,"
 by W. B. Ewer, editor of PACIFIC RURAL
 PRESS. In addition to these lectures a course
 is now being delivered at the Mechanics In-
 stitute in this city by some of the Professors of
 the University. These lectures are of course
 free to all.

WM. A. STUART, of Napa county, has sold
 his one-twentieth interest in the Geyser and
 Mercury mines to Wm. H. Sears, of San Fran-
 cisco, for \$30,000, or at the rate of \$600,000 for
 the two mines.

QUICKSILVER has fallen in Liverpool to £23
 per flask.

The Hair Worm, or Horse-Hair Snake.

A lady friend, who resides on Russian Hill,
 has sent us a lively specimen of that singular
 species of animated nature, commonly known
 as "the hair worm," or "horse-hair snake."
 It came into the possession of our friend from
 the faucet in her dwelling, connected with the
 Spring Valley water works. She intimates that
 it is just a little dangerous to indulge in aque-
 ous potations from the faucet in the dark. We
 should think it was. In answer to her inquiries
 as to its origin, and how it came all the way
 through the pipes, we append the following:

Most of our readers are doubtless familiar
 with the form and appearance of this singular
 worm or snake, and many of us, when boys,
 and some of us when full grown men and
 women, were fully impressed with the belief
 that a hair from a horse's tail, when left in a
 pond or other still, warm water, would turn in-
 to one of these singular creatures. It has been
 a popular belief that if incautiously handled, it
 will bite the ends of the fingers and occasion
 that peculiar sore, or gathering called a whit-
 low. But the microscope shows that it has
 neither jaws nor other instruments by which it
 can either bite or sting. Indeed, it has not even
 a mouth—but obtains its sustenance by the
 absorption of fluids through a membrane over
 that part of its body where the mouth should be.
 Joseph Leidy, a well known Philadelphia pro-
 fessor, once tried a series of exhaustive experi-
 ments to prove that this popular notion of its
 origin could not be true. The microscope and
 scientific investigation, however, have more fully
 proven that this, like every other living crea-
 ture, springs from an egg in the first place.

Science informs us that this is not an insect,
 but belongs to that class of parasitic worms,
 which live and thrive, for a certain length of
 time in the intestines or substances of some
 other body, like the tape worm in the human
 system and the trichinae in the hog. The name
 of the genus to which this worm belongs is *Gordius*,
 and there are quite a number of different
 species. The most common species of this
 genus, and that to which the one now before us
 belongs, live in the bodies of grasshoppers,
 crickets and various other insects; but when
 nearly mature and full grown, they bore their
 way out of their insect home, and take to the
 water or moist earth, where after a few days
 they lay their eggs, which are almost innum-
 erable. They are laid in long strings, which look
 like very fine, white sewing cotton. One of
 these worms was seen by Professor Leidy,
 while he was experimenting, to lay a string
 ninety inches long! These eggs are exceedingly
 small—so small that upwards of 1,200 of them
 have been counted in one forty-fifth of an inch
 as thus laid in a string. This would give some-
 thing like six millions of eggs as the product of
 the single worm observed by Prof. Leidy.

The eggs, exposed to the warm summer
 sun, hatch in about one month, and liberate
 worms which have very little or no resemblance
 to their parents. The Professor, during his
 investigation, succeeded in hatching several
 eggs. They produced small tadpole-shaped
 creatures, with a spine and two circles of sharp
 hooks—six in a circle—which could be pushed
 in and down out from the head. This forms a
 kind of boring apparatus, by which the tad-
 pole can penetrate the bodies of such insects
 as may approach them. The Professor placed
 some of the larvæ of May flies in the vessel in
 which the eggs were hatched, and soon the
 young tadpole *Gordius*, were seen to bore their
 way into the larvæ. They were also seen to
 penetrate the delicate membrane at the joints
 of the legs of crickets and grasshoppers which
 were confined and placed in the vessel. They
 were carefully watched, and it was found that
 they gradually ascended among the muscles
 and other organs of the bodies, strongly
 reminding one of the similar but slower move-
 ments of trichinae in the muscles of man and
 the hog.

Of course, their change from the tadpole
 condition to the worm, takes place within the
 body of the insect in which they take up their
 temporary home, living and increasing by the
 nutritious fluids there found until nearly or
 quite fully grown. That such is the case has
 been verified by a report from Mr. Justus Gage,
 who some years since wrote to the Michigan
 Farmer, as the result of his observations, that he
 had discovered that the cricket resorts to the
 water during the month of August to rid itself
 of its unwelcome intruder. Mr. G., had
 been led to believe that the hair worms, which
 were numerous in a certain locality, issued
 from the bodies of crickets, which were also
 numerous in the same locality, although he
 was unacquainted with the manner in which
 they found their way into the crickets.

One day, after he had been experimenting
 by placing crickets in the water to obtain hair
 worms from them, and had succeeded in securing
 two specimens, he noticed a cricket crawling
 up the side of his water pail. It jumped into
 the water, lay quiet for a moment, produced a
 hair worm some six inches in length, and then
 made its escape nimbly over the edge of the
 pail. About the same time he found a worm
 some seven inches long in a dead cricket which
 he found under a stone.

Notices of Recent Patents.

Among the Pacific coast patents recently
 obtained through Dewey & Co's MINING
 AND SCIENTIFIC PRESS American and Foreign
 Patent Agency, the following are worthy of
 mention:

ROAD ENGINE.—R. R. DOSH, Sacramento.
 This invention is an improvement on road en-
 gines, and consists in so connecting the engine
 bearing portion of the machine with the front
 or steering part, that the driving belt wheel
 upon the latter will always remain in the
 proper position to receive the belt from the for-
 mer; whatever change in angle and direction
 may be given to the machine. The chassis and
 wheels for receiving and imparting motion from
 the engine, are also of novel construction.

BLIND SLAT ADJUSTER.—Aaron David, Ma-
 rysville. This invention is to improve the de-
 vice for adjusting the slats of window blinds on
 which an arm on one end of a crank shaft is
 made to raise and lower the rod which connects
 the slats, so that the slats can be adjusted and
 retained in any desired position. The improve-
 ment consists, first in securing the crank shaft
 in a suitable box upon the top or upper edge of
 the lower rail of the blind frame instead of to
 its side as heretofore, and secondly in an im-
 proved method of connecting the arm with the
 connecting rod of the slats.

IMPROVED GRIDIRON.—James H. Mitchell,
 San Francisco. The object of this invention is
 to provide a gridiron for broiling, which can be
 readily repaired in case any portion of it should
 become worn out or destroyed by use. The in-
 vention also includes an improvement by
 which the bars of the gridiron are prevented
 from being warped and bent by the heat to
 which they are subjected.

MORTISING TOOL.—Gustave Eolin, San Fran-
 cisco. In the manufacture of furniture it is
 often difficult to make a respectable mortise or
 socket for the reception of the bolt of the lock,
 which locks the drawer when it is closed, owing
 to the limited space, (only the depth of the
 drawer) in which the workmen is required to
 accomplish the work, it being necessary to
 make the bolt socket after the piece of furni-
 ture is completed, the drawers fitted and the
 lock secured in place. Ordinary chisels and
 mortising tools cannot be manipulated in this
 narrow space, and as a consequence the mor-
 tise had to be made by holding the chisel or
 other tool at an angle so that its lower end
 would be outside of the drawer, space or open-
 ing. The outside wall of the mortise thus con-
 structed would also be made at an angle or
 bevelling so that it answers imperfectly as a
 bolt socket. This improved mortising tool is
 intended to avoid this difficulty by supplying
 an implement which can be handled in a nar-
 row space to make a mortise or socket.

SHEEP SCRATCH BOX.—Ira B. Dillon, Visalia.
 This invention is a novel device for applying a
 healing ointment to the backs of sheep which
 are afflicted with scab or other sores, and con-
 sists in the use of a containing vessel within
 which the ointment is placed and it is retained
 by valves at the bottom. A series of pointed
 spikes project downward from the bottom of the
 box which is placed at a convenient height so
 that the animals can pass beneath it and the
 operation of scratching their backs will open
 the valves so as to allow a portion of the con-
 tained liquid to run out upon the back.

LAMP CHIMNEY GUARD.—Robert Priseman,
 Sacramento California. This is a device for
 guarding lamp chimneys on ship-board or rail-
 way cars and in other places where lamps are
 subjected to a motion which is liable to cause
 their chimneys to fall off. The invention con-
 sists in supporting a metal ring in such a man-
 ner either from the ceiling of the car, boat, or
 other structure or edifice or from some other
 convenient support, so that it will encircle the
 upper end of the chimney and prevent it from
 falling or being thrown from the lamp by any
 motion or jar.

THE California Academy of Sciences held its
 annual meeting at the University of California
 on February 22d. Invitations were issued to
 the Board of Regents and Faculty of the Uni-
 versity, officers of the Mechanics' Institute,
 trustees of the Lick estate, Microscopic Soci-
 ety and of gentlemen otherwise prominent in
 scientific, literary and educational affairs.
 Professor Joseph LeConte read a paper on the
 "Glaciers of Lake Tahoe," the result of origi-
 nal research and observation in that region.
 Professor John LeConte gave a brief descrip-
 tion of two new pieces of apparatus lately pro-
 cured by the University. Dr. Kellogg read a
 short paper on "Hops." A paper on "The Origin
 of California Land Shells," by J. G. Cooper,
 was read. Resolutions were adopted expres-
 sive of the relations between the Academy and
 University, and congratulating the University
 on its progress. After the meeting the guests
 amused themselves examining the groves and
 buildings, and discussing a collation. A very
 pleasant day was spent.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Fifth Lecture Delivered before the University of Cal-
 ifornia College of Agriculture, on Friday, January
 22d, by PROF. C. E. BESSEY.

Insect-Using Plants.

In that suggestive little book of Dr. Gray's,
 "How Plants Behave," some curious things
 are told about plants and insects. One chap-
 ter tells "How plants make insects work for
 them;" another, "how plants capture insects."
 Within the last few years the attention of bot-
 anists has been directed to the relation be-
 tween plants and insects. Darwin, in his
 book, which is too little known in this coun-
 try, "On the Fertilization of Orchids," showed
 that in orchidaceous plants, in every case
 almost, it is absolutely necessary that insects
 should carry the pollen from the stamen to the
 pistil and that in all cases the plants and in-
 sects were

Mutually Adapted to Each Other

And that each species of plant had each its
 particular insect, each corresponding exactly
 to the other. These facts have given to or-
 chids an interest not excelled by any other
 group of plants. For some time they were
 looked upon as somewhat exceptional in their
 need of insects. This peculiar subject has
 been well studied by Darwin, Miller, Lubbock
 and others and by them we have been shown
 that this dependence upon insects is not con-
 fined to orchids, but that on the contrary, very
 many of our ordinary flowering plants are just
 as dependent as these same orchids.

Now, a little about fertilization. The fer-
 tilization of flowers is usually effected by the
 association or union of two cells, the stamen
 or pollen cell, and the pistil or ovule cell.
 Pollen is contained in pollen sacs on the sta-
 mens, while the other cells are found in the
 cavity of the ovule. The pollen in fact comes
 in contact usually with the stigma and then
 grows down through the soft tissues to the
 ovule cell. The deposition of pollen, then,
 upon the stigma is a matter of great impor-
 tance. If it is allowed to fall upon the stigma,
 fertilization ensues; if it is prevented, there
 can be no fertilization and just here is where
 the work of insects comes in.

Now it might be supposed that each flower
 would be made so that its pollen would fall
 upon its stigma, and for a long time this was
 supposed to be the case, and then the point
 was shown that in every case the pollen
 would fall upon the stigma.

It was found in many plants that the stamens
 and pistils are in different parts of the branch-
 es; that is, they are dioecious, as we call them.
 In some cases the stamens are in one plant
 and the pistils in another. Now then, if na-
 ture intended the pollen to fall upon the stig-
 ma, this certainly is not the best arrangement
 to produce that result. In Iowa we have a
 very beautiful plant, the Claytonia, or Spring
 beauty. When it opens, the stamens are shed-
 ding their pollen. Examining the flower at
 this time, it has pretty generally the appear-
 ance of a, Fig. 1. At the time these stamens
 are shedding their pollen, the lobes of the stig-
 ma are closed up. Now, the stigmatic surfaces
 are in the inner parts, that is, they are brought
 together in their closing of the lobes, so that
 when these stamens are shedding their pollen,
 it can not possibly get upon the stigmatic sur-
 faces. In ten or twelve hours or more, these
 stigmatic lobes begin to diverge. But now see
 what follows. Just as soon as these begin to
 spread, the stamens assume the position shown
 at b, Fig. 1, that is, they are preared down flat
 against the petals, as far away as possible from
 the stigma. As soon, however, as the fertili-
 zation has taken place, the stamens again as-
 sume their original position, showing con-
 clusively that we have here an action to pre-
 vent this pollen getting upon these particular
 stigmatic lobes.

Then, you have here another case, which is
 quite common. I see, growing all along the
 roadsides, the plantain. [The speaker then
 pointed out with the aid of diagrams the pecu-
 liar arrangement in the plantain for prevent-
 ing the pollen of one flower from reaching the
 stigma belonging to that flower.] Now, in
 these two cases that I have pointed out, it looks
 very much as if it was intended that stamen
 and stigma were to be kept apart, or, as Dr. Gray
 expresses it, "as if the object were *hove not to do it*." There is no doubt that in a large num-
 ber of cases the stamens and the stigmas are
 kept apart, so that the flower shall not be

Fertilized by its Own Pollen,

And in such cases there are generally special
 arrangements made for bringing pollen from
 other flowers. In carrying out this, insects
 have a very important office. When an insect
 visits a flower, it does not simply go there to
 get honey. There are two objects. The in-
 sect gets honey for itself, and in turn it car-
 ries pollen for the flower.

I will now call your attention to a few plants
 that you may meet. I think none of them are

plants but that you can examine for yourselves. The first, is *Viola Tricolor*, the little pansy, or heart's-ease. This is the little, cultivated flower, considerably changed from the wild flower, which is found in Europe, but universally known as the pansy. And after I have told you what I have to say about these, you can make your own examination and verify my statements. I have here some diagrams to show its principal peculiarities. One peculiarity is that, take the plants as they grow wild, they grow in two forms; a large form and a small one. Now one form is large enough so that insects can visit it, but the small form is too small, so it has to take care of itself.

[The Professor then by the aid of numerous figures explained the structure of the large form of the violet, showing clearly that the pollen from any flower could not possibly fall upon or onto its stigma, but that there were special contrivances and lures for enticing the insect into certain parts of the flower, and then compelling it to carry pollen to the stigma of the next flower. On the other hand it was shown that the small-flowered form, being too small for insects, had to shift for itself; hence it is so modified that its pollen can fall upon its stigma—in other words it can fertilize itself.]

The plants belonging to the genus *Primula*, or the primroses, show some peculiarities. I have here figures showing the peculiarities of the primrose. (See Fig. 2.)

In this case we have what is called dimorphism; that is the flowers grow in two forms. The little pansy just spoken of gives you an idea of what one kind of dimorphism may be; here, however, we have another kind. By referring to Fig. 2 it will be seen that the dimorphism of the primrose relates to its stamens and pistils. In one form (shown at a) the style reaches to the top of the corolla, while the stamens are situated near the middle; while in the other form (shown at b, the style is short and the stamens are situated at the top of the corolla.

Now the explanation of it is quite simple. We find that these are always visited by insects. The arrangement is simply in order to prevent the pollen which grew in these stamens from getting upon the stigma. In all such cases, honey is placed

Down in the Bottom of the Flower.

The insect, in search of honey pushes the style of a to one side and crowds by the stamens; there it wriggles around, gets itself thoroughly covered over with the pollen and then gets back. Now it goes to the other form shown at b, enters it, and you will observe that here the stigma is just at the same height as were the stamens in the other, so that the pollen-covered portions of the insect's body will come in contact with the stigma and so cause fertilization to take place. Observe that the positions of stigma and stamens are corresponding, so that they readily can cross-fertilize.

Here, the plant takes on the habit of producing different kinds of flowers, almost always on different plants, but always belonging to the same species, for the purpose of engaging insects to carry its pollen.

[The structure of the *Drum*, an endogenous plant, was then explained with the aid of diagrams. It was pointed out that the flower first entrapped the insects and kept them prisoners for a time, when having need them as much as it wanted to, it secreted a few drops of honey for them as a peace offering and then let them go.]

There are peculiarities in the common barberry which have long attracted the attention of botanists and a great many others. [The Professor then referred to illustrative diagrams.] Now, it has long been known that when the stamens are touched, they will on account of their irritability, move up to the center of the flower with a quick jerk. If you take a pin and touch them, down at their base, they will very suddenly fly up close to the pistil. I suppose this is known to everybody who cultivates the barberry. This was formerly supposed to be an excellent arrangement for securing self-fertilization. Somebody, however, after Mr. Darwin began his shrewd and careful investigations, found that the stamens were not quite long enough to secure self-fertilization. Now, the arrangement, if we look at it from another standpoint is a very efficient one. I suppose that if the botanists of twenty years ago had discovered that the stamens were too short for self-fertilization, they would have supposed it was a blunder or something else like it, in nature. We now know, however, what it means. At the bottom of the stamens is placed a honey gland. Insects coming and plunging down into the flower always strike the stamens which makes them suddenly start up. The result is, the insect is

Covered Over with Pollen.

Now, when the insect gets thoroughly covered over, it goes to the next flower, plunges down on it and it cannot fail to leave some of the pollen there and so it goes from flower to flower carrying pollen from one to the other.

Another plant which you can readily find, is the little *Portulaca*, often called moss rose. It is somewhat like the barberry, only that in this case the stamens are still more sensitive.

In the sage, the one grown for its flowers, *Salvia officinalis*, we have only two stamens and they are made on a peculiar plan, having a hinge-like arrangement allowing one part to rotate upon the other. It belongs to the labiate group, and has its lower lip made very large to serve as a "lighting board," as Mr. Darwin has called it.

[Here again, by the aid of drawings, the speaker explained that when an insect attempted to enter the flower, it rotated the stamens in such a way that the pollen was thrown on the back of the insect, where upon visiting other and older flowers it would come in contact with the stigma.]

In the orchids, the arrangements are in some cases exceedingly complex, and frequently this mechanism is such as to almost pass belief; that is, it seems almost impossible that a flower should have such peculiar contrivances just for the purpose of getting its pollen upon some peculiar insect. As a rule, they are incapable of self-fertilization. That is, if insects or other

Claytonia in its First and Second Stages.

active agencies were taken away, in almost all cases, fertilization could not take place. I told the class yesterday about the vanilla plant, which was taken from America to the East Indies, but in so doing they neglected to take the insect along, and the result was, the culture of the vanilla there was not a success, until some shrewd man guessed the trouble, and took the insects along, when vanilla growing became successful. Orchids are, in almost all cases, gayly colored, or they have peculiar forms, peculiar odors or an abundance of honey—

something about them always which is attractive to insects. You may

Lay it Down as a Rule

That when a flower has need for an insect to visit it, it will hold out some inducement for that insect to come.

The arrangement of the parts of the flower is

Fig. 3—Blow-off Used in Low Places on Line of Pipe.

always complex in the orchids, so that usually the young botanist is puzzled in getting at their structure. [The Professor then, by means of numerous drawings, explained the intricate structure of orchids, and the various contrivances which aid in securing fertilization through insect agency.] Sticky pads attached to pollen masses, are so placed as to adhere to the heads of insects visiting the flowers for their honey; and these pollen masses are then carried by the

Dimorphism of the Primrose. a, Long-styled Form. b, Short-styled Form.

insect to the next flower; by which time they have actually bent down at

Just the Right Position

To enter the surface stigmatic. In other cases, as in the lady slipper, the insect is compelled to go into the flower at one door and to go out at another; bringing in at one door pollen from one flower to be left, and carrying out at the other, pollen to be taken to the flower next visited.

CORRECTION.—In the short editorial comment on the "Extraordinary Change of Temperature," which appeared in our Scientific column last week—"down pour of snow," should have read "down pour of cold air."

In Utah, although there has been a considerable quantity of snow in the mountains, mining operations have continued without interruption, and much more ore has been taken out than during any previous winter.

A new 15-stamp mill is being erected at Forbestown, Butte county.

Double Fish.

The State Fish Commissioners have recently erected in the grounds of the University of California, at Berkeley, a fish hatching house, and many thousands of ova and young brook trout may be seen in the troughs. It is proposed to build dams at favorable points in the creek and its branches, for the double purpose of protecting the banks and furnishing ponds

Fig. 2—"Shingle Roof" Pipe.

for the fish. These young Eastern trout are fast being distributed in different streams in the State, by Mr. Woodhury.

While examining the hatching boxes at the propagating house one day this week we noticed several of the little trout, which are scarcely an inch long, presented a peculiar phenom-

non. In some cases there were two distinct heads and only one tail. In others there were two distinct fish, but formed together by a filmy substance, after the manner of the Siamese twins, except that the tissue extended the whole length of the body. These little fellows were swimming about without any apparent

feeling that there was anything wrong. If they felt any difference of opinion as to the direction they wished to swim it was not manifest, as a double fish and two headed fish were apparently contented. These fish are now six weeks old, and several dozen were in the troughs.

Fig. 4—Self-Acting Air Valve.

The eggs from which these fish were hatched were brought by rail from the East. We understand that the same phenomenon occurred with the fish hatched from the salmon eggs taken from the McCloud river here and transplanted to the East. Those eggs were also taken by rail, and many of them hatched out double fish, as in the case of the eggs hatched at the University. We do not know of any case where such a circumstance has happened before, or at any rate where such numbers of double fish were hatched out. No doubt it may be attributed to the railroad journey of the eggs from which the fish were hatched, as some of them may have been jarred in such a manner as to become mingled together. We cannot otherwise account for the phenomenon,

Hydraulic Mining in California.

No. 14.

Iron Pipes.

In such constructions the entrance of any floating matter should be prevented by a screen of strong wire, or iron bars, placed at some distance from the mouth of the pipe. Particularly in the autumn, when the leaves fall, care should be taken to remove the latter, whenever a quantity is collected before the screen.

The standing air-pipe mentioned above has not proved efficient for the escape of all the air which is carried down by the water. The consequence is, that from time to time, the accumulated air makes an attempt to free itself, and, in doing so, rushes up the stand-pipe with great force, throwing out a large quantity of water, and even emptying the cistern.

The writer thinks a very simple arrangement would secure the undisturbed flow of water, and permit the air to escape as it accumulates, without interfering with the water rushing into the pipe. The water will form a solid body in that part of the pipe, which is filled from the lowest depression of the inverted siphon to an equal height, or level, in each arm of the pipe.

In the diagram (Fig. 4) the undisturbed water would rest below the points A A', and only from A2 to B could air interfere with the free admission of water. According to the great or less supply of it, the water would rise or fall between A2 and B; and the stand pipes, represented by D E F, would not only become valueless, whenever the water should rise to the point of their connection with the main pipe, but would, under circumstances, discharge great quantities of water, whenever the latter should have risen in the main pipe above their height. Furthermore, there would be no continuous discharge of air, as the resistance of the flowing water against the escape of air would be comparatively as great between points G H or H I, as between A1 and B. An arrangement is therefore needed, which will not only permit the air to escape at any point between A and B, but also prevent the rushing water from interfering with the free discharge of air.

The writer proposes a simple plan, as illustrated by figure 2.

The circle A represents a pipe 30 inches in diameter, the line B C a piece of sheet iron, 23 inches wide from B to C, and 5 inches below the point D. This piece of sheet iron enters the pipe on a bevel, for a distance of two and a half or three feet, falling in this distance one inch. The sides B C are securely riveted to the pipe. A second piece of sheet iron must be inserted in such a way that the first piece overlaps it for about 2 inches, leaving at the same time an open space of one inch in depth, and 24 inches in length between the two pieces of sheet iron, where the overlapping takes place. Any number of additional pieces of sheet iron are inserted in the same manner, forming, as it were, a shingle roof on the top of the pipe, with an open space of one inch in depth and 24 inches in length between each two shingles.

The water enters at the point a, and is prevented from entering the air-chamber by the overlapping of the different iron shingles; the air, however, will, under the least pressure, escape through the open spaces, between the iron shingles, and can be conducted to any final outlet, without interfering in the least with the rush of water.

This air-chamber needs only to be constructed in a little above that part of the pipe which is subject to the rising and falling of the water, according to the greater or less supply. For instance, in a pipe like that of the Spring Valley Canal and Mining company, constructed for a head of 150 feet—when experience has shown that a hydrostatic pressure of never more than 50 feet is realized—the shingle roof, or air chamber, needs only to be applied from near the "solid water" in the bottom of the pipe to a point giving a vertical height of 75 feet above the "solid water." Of this distance, only 50 feet or less would be filled with water, to form the head or hydrostatic pressure, and the remaining 25 feet would secure a sufficient vent for all the air which possibly might come down with the rushing water.

It will be seen that the capacity of the pipe is not lessened by the introduction of the air-chamber; the latter consisting of nothing but pieces of sheet iron riveted from side to side, and permitting the rising water to fill the air-chamber from below, and thus to occupy the whole capacity of the pipe. The arrangement in itself is simple, and can be introduced into any pipe already in position, provided it is large enough to admit a workman.

For pipes conducting water to the hydraulic machines in the mines, the following plan is recommended to get rid of the air: A pipe of 4 or five inches in diameter is perforated with holes, each, say, of 2 inches diameter, and at intervals of two and a half or three feet. These holes are covered with caps of the shape of half-funnels, and in such a way that the wider part of the funnel leaves an open space, lap-

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they
 have no equal. No effort has been, or will be spared
 to have them constructed in the most perfect manner
 and of the great number now in operation, not one has
 ever required repairs. The constant and increasing de-
 mand for them is sufficient evidence of their merits.
 They are constructed so as to apply steam directly
 into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
 The pan being filled, the motion of the muller forces
 the pulp to the center, where it is drawn down through
 the aperture and between the grinding surfaces.—
 Thence it is thrown to the periphery into the quicksilver.
 The curved plates again draw it to the center, where it
 passes down, and to the circumference as before. Thus
 it is constantly passing a regular flow between the grind-
 ing surfaces and into the quicksilver, until the ore is
 reduced to an impalpable powder, and the metal amal-
 gamated.

Sellers made on the same principle excel all others
 They bring the pulp so constantly and perfectly in con-
 tact with quicksilver, that the particles are rapidly and
 completely absorbed.

Mill-men are invited to examine these pans and sellers
 for themselves, at this office, 229 Fremont Street,

Ayer's Sarsaparilla,
 FOR PURIFYING THE BLOOD.

This compound of the
 vegetable alternatives, Sarsa-
 parilla, Dock, Stillingia and
 Mandrake with the Iodides
 of Potassium and Iron
 makes a most effectual cure
 of a series of complaints
 which are very prevalent
 and afflicting. It purifies
 the blood, purges out the
 lurking humors in the system, that undermines health
 and settle into troublesome disorders. Eruptions of
 the skin are the appearance on the surface of humors
 that should be expelled from the blood. Internal dis-
 arrangements are the determination of these same humors
 to some internal organ, or organs, whose action they
 derange, and whose substance they disease and destroy.
 Ayer's Sarsaparilla expels these humors from the
 blood. When they are gone, the disorders they produce
 disappear, such as Ulcerations of the Liver, Stomach,
 Kidneys, Lungs, Eruptions and Eruptive Diseases of the
 Skin, St. Anthony's Fire, Rose or Erysipelas, Pimples,
 Pustules, Blotches, Boils, Tumors, Tetters and Salt
 Rheum, Scald Head, Ringworm, Ulcers and Sores,
 Rheumatism, Neuralgia, Pain in the Bones, Side and
 Head, Female Weakness, Sterility, Leucorrhoea arising
 from internal ulceration and uterine disease, Dropsy,
 Dyspepsia, Emaciation and General Debility. With
 their departure health returns.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor, also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorina gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

CROCKER'S PATENT

TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, five steel arms with stamps weighing 17 lbs. each, which strike 2,000 blows per minute, in a mortar provided with screens on both sides, and crushes FINE 600 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$500.

G. D. CROCKER,

17v26-4f

815 California street, San Francisco.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supls. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness in first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 30 days to fill orders from the manufacturing East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

1v29-3m

CAST STEEL SHOE & DIE CO., Room 1, Academy Building.

THE AMERICAN TURBINE WATER WHEEL

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{4}$ 50.08; $\frac{3}{4}$ 69.64; $\frac{5}{8}$ 78.73; $\frac{3}{8}$ 82.53; $\frac{1}{2}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

BALL'S SWEEPING DREDGE,

A NEW AND VALUABLE

CALIFORNIA INVENTION,

Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work.

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, &c., all complete; therefore I am proposing to ask nothing for my patents unless any machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address, JOHN A. BALL,

Oakland.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

(Continued from Page 137.)

ping about one inch over the hole. The pipe thus prepared is inserted from 50 to 100 feet, according to the length of feeding pipe, into the latter, the open funnel downward, and is secured firmly to the upper side of the feeding pipe. The upper end of this air pipe must rise a few feet above the hulk-head from which the feeding pipe is supplied.

The air which necessarily enters the feeding pipe with the rush of water will seek the easiest way of escape, and must, consequently, enter the inserted pipe through the open funnels. The caps over the holes of the air pipes prevent the water, rushing down, from entering the air pipe, and the air can be conducted safely to a final outlet.

The above arrangement would not lessen the capacity of the feeding pipe, as the water, rising in the latter, would enter the air pipe through the funnels, and rise in both pipes simultaneously.

The advantage to be gained from this arrangement would be the almost total exclusion of air from the feed pipe, and, therefore, the certainty of a solid and even discharge of the water from the hydraulic machine, securing the greatest efficiency and force of the water jet.

[In addition to what Mr. Waldeyer says above, we give in Figures 3 and 4, the methods of regulating the air in pipes in use by the Virginia and Gold Hill water works. At their water works the body of water passed through an inverted syphon over seven miles long on very irregular ground, in doing which the enormous pressure of 1,720 feet has to be overcome. This pipe now contains the greatest pressure of any in the world. The average diameter is 11 1/2 inches. At the point of heaviest pressure the iron is No. 0 thick, and is but riveted with five-eighths inch rivets. The pressure is 1,720 feet perpendicular, or 750 pounds to the square inch. This pipe crosses a great many sags and spurs, and devices had to be arranged to relieve the air. Figure 3 shows the blow off used in every low place and Figure 4 shows the self acting air valve. The latter is used at each high point on the line of pipe. When the water is on, the valve, *a*, is kept wide open; the small valve, *c*, is shut, while the valve, *b*, is shut by the pressure. If any air accumulates in the pipe, on the elevation where this air cock is placed, it is occasionally blown off, by opening the cock, *c*. Should a break occur in the main pipe line at a point lower than the air cock, and within its district, the valve, *b*, falls down and admits the air into the main pipe so as to prevent a vacuum. Should the valve, *b*, get out of order, the valve, *a*, is shut, and the other valve, *b*, taken off and repaired. After a break on the main line is repaired, and the water let on again, the valve, *b*, being down or open, the air rushes out at *b*, its stem being weighted by the weight, *d*, so as only to close when the solid water commences to rush out. We gave a detailed description of the works above referred to, in our issue of Dec 13th, 1873, and give here what refers to the blow off's and air valves, as supplementary to Mr. Waldeyer's remarks.—*ENS. PRESS.*]

The Auburn mill at Reno, has been closed down. The lessees, Messrs. Riott and Beyea, being unable to pay the high rent charged by the English owners. Moreover, although they worked the ore satisfactorily, they could not procure enough to keep the mill steadily running on full time. If they had been able to get all the ore they wanted, the mill would still be running, notwithstanding the high rent. Mr. Riott has returned to this city, and is engaged in his old business of assaying and working ores. We are sorry to know that the experiment has been a losing one to the lessees.

DR. ST. GEORGE HOPKINS, of Virginia City, has invented a new style of ore car. It dumps itself, and if, in being run back to the shaft, the cage is missed, it precludes all danger to the carman of falling down the same by overturning and occupying all the open space in the shaft.

The New York Consolidated mining company has contracted for first-class machinery for their mine, of sufficient power to sink down to the depth of 3,000 feet, being fully equal to the machinery of Belcher and Overman, and of the same pattern as that now used by the California.

MINING interests in Lower California are looking up considerably. Some 20 persons have arrived at San Diego recently, for the purpose of prospecting in Lower California. Two old miners, Messrs. Mulligan and O'Reilly, have made a rich discovery near San Rafael, which promises well.

The Spring Valley canal and mining company, of Butte county, advertise for bids to construct a double line of levee embankment for a distance of about nine miles.

ENGLISH capitalists are negotiating for the iron mine recently discovered in Snoqualmie Pass, Washington Territory.

SIR CHARLES LYELL, the geologist, died in London, on the 23d inst.

ANTIMONY is selling at \$52 to \$54 per ton or regulus in Liverpool.

General News Items.

FIRE AT THE SARATOGA PAPER MILL.—A correspondent of the San Jose Mercury reports that on Friday night, the 19th inst., the immense straw stacks of the Saratoga Paper Mill company were destroyed by fire. The estimated loss is \$10,000. The company had laid in a supply sufficient to keep the mills running all summer, and its sudden destruction throws about twenty men out of employment. The fire is supposed to have been the work of an incendiary, and the company has offered a reward of \$1,000, and the citizens of Saratoga \$500, for the arrest and conviction of the culprit.

FIRE IN GOTTENBURG—51 LIVES LOST.—A match factory in Gottenburg, Sweden, took fire on the 10th inst., when crowded with work people. The flames spread with such rapidity that the employees on the upper floors were unable to escape, and many were burned to death or killed by jumping from the windows. Fifty-one lives are reported lost.

POSTAL CHANGES.—The following postal changes were made in California last week: Postoffice established—At Salmon Falls, El Dorado county, Thomas Orr, Sr., Postmaster. Postmasters appointed—Hiram T. Hatch, at Sherwood Valley, Mendocino county. John C. Partridge, at Susanville, Lassen county.

DESTRUCTIVE FIRE.—A terrible fire broke out at Port-au-Prince, Hayti, on February 11th, and spread with most alarming speed. Two-thirds of the city was destroyed in a few hours, involving a loss of about \$2,000,000. From 600 to 700 families were rendered homeless.

EXPLOSION—FIVE GIRLS KILLED.—An explosion occurred at a safety-fuse manufactory at Redrath, Cornwall, (Eng.,) on Saturday last, at which five girls were instantly killed. There were quite a number of almost miraculous escapes.

The Centennial arrangements are progressing finely. The expenses of the building have been cut down very materially from the original estimates—but they will be all that is really needed, either for performance or utility when they are completed.

The narrow gauge railroad from Colfax to Nevada is now well under way. The only question which remains to be settled is whether Nevada shall be the terminus. Mr. Beatty, the contractor, has sent East for the rails and locomotives.

LIBERAL DONATION.—Mr. August Hemme, of this city, has given \$30,000 to free the Tehachan church in this city from debt. He has also presented the publishers of the *Occident*—a religious newspaper—with \$500.

The young wife of the newly-elected United States Senator, James E. McDonald, of Indiana, died suddenly in Indianapolis on Thursday. She was married only six months ago.

A NOVEL LIFE PRESERVER.—A Chinaman, after the wreck of the "Japan," was rescued from a coffin which he had improvised as a life-preserver.

CREMATION.—The Municipal Council of Paris on the opening of the new cemetery at Mery-sur-Oise petitioned the legislative power for permission to practice cremation.

CLAUDIO VASQUEZ, brother of the handit, has held the position of Justice of the Peace in Los Angeles county. He is said to be a good citizen.

SUICIDE BY A WOMAN.—The wife of Edgar E. Bliss committed suicide by taking strychnine on Tuesday, the 16th inst., at Danville's ranch, on the Honcut.

HENRY S. DENT, son of G. W. Dent and nephew of President Grant, died at his residence in this city on Sunday evening. He was 31 years of age.

The San Rafael Herald states that an opposition steamer will soon be placed on the route between that town and San Francisco.

DEATHS OF THE WEEK.—Seventy-five persons died in this city, last week—seventeen in hospitals, etc., and one homicide.

A FIRE destroyed property at Kenton, Ohio, on Thursday of last week, to the extent of \$200,000.

The Selinas and Monterey railroad will be making regular trips again within two weeks.

CONGRESS.—The present Congress expires by limitation on Wednesday next.

JESSE POMEROY, the hoy murderer has been sentenced to be hung.

QUARTZ is the only thing that is talked about in Southern Oregon just now. Constant discoveries are being reported and the people are being kept in a constant state of excitement, and employ their leisure hours between making discoveries and building golden castles in the air.

INQUIRE BEFORE YOU DETERMINE.—Ask your druggist what *Hale's Honey of Horshond and Tar* is doing in cases of severe cough and cold within his own personal knowledge, before you try it yourself. Inquire of him if he has ever known a medicine of his class as popular as that pure and agreeable vegetable preparation. Be governed by the facts he will state to you. We venture to say that there is not an apothecary in the country who will not endorse it as a specific for diseases of the lungs and throat.

Hale's Tooth-Ache Drops—Cure in one minute.

Industrial Items.

PAPER BARRELS.—Although the process of making barrels from paper was patented only about two years ago, there are now two factories working; one at Winona, Wis., and the other at Decorah, Iowa, the latter turning out 1,600 barrels per day. There will be another in operation in this city in a few weeks.

The bevel-screw or ship-timber saw, which the Ship-building Association of Vallejo has ordered from the East, will be the only one of the kind on the Pacific coast, excepting at the Navy Yard. It is a most valuable invention, and will do the work of over twenty men.

It is now settled that the people of Peudleton, Oregon, are to have a woolen factory. Articles of incorporation have been filed, and all the necessary steps taken preparatory to opening hooks for stock subscriptions.

A PRISMOIDAL.—There was a railroad meeting in Sonoma, last week, to consider the question of building a prismoidal railway from the town of Sonoma to the Embarcadero.

WAVE POWER MACHINE.—The working model of the above machine is now on exhibition at the Merchants' Exchange.

The Cornell Watch Factory managers say that but two Chinamen are in their employ, and these merely as common laborers.

A PHILADELPHIA company are making arrangements for the establishment of a large agricultural manufactory at Ogden this spring.

A NEW locomotive has just been received from the East for the Monterey and Salinas Railroad.

The Pacific Bridge Company have contracted to build the trestle work at the Yuba river bridge during the next thirty days.

OPERATIONS on the fruit drying establishment to be erected in Napa will commence on Monday next.

VISALIA offers a block of land and \$5,000 to any person who will erect there a woolen mill worth \$30,000.

The Hollister Bank, organized five months since, has declared a monthly dividend of 1 1/2 per cent.

SAN MATEO COUNTY claims fifteen millionaires, the aggregate of whose wealth may be estimated at \$250,000,000.

The Carmel Whaling Company, of Monterey, have done a brisk business this season.

SALINAS CITY is discussing the advisability of having a local telegraph.

A WOOLEN mill and broom factory are to be established at Knight's Landing.

CANNING oysters is a successful enterprise at Yaquina.

LEAD in Liverpool has declined 15s per ton since the 1st of January, owing to large receipts of foreign. The closing quotations on the 1st inst. were £23 and £23 5s for good ordinary brands.

The Eagle Mill at Spring Valley, Nev., has been put in order for wet crushing. A Blake crusher has also been put up at the mill.

A VEIN of black lead has been found in the Baton Mountains, Colorado, and the owners have refused \$50,000 cash for it.

THERE are 3,000 Chinamen at work in the mines at the Lava Beds, near Oroville, Butte county.

MINING operations in Baker county will be conducted on a larger scale this year than ever before.

At Winnemucca the strike in the Pride of the Mountain tunnel, is creating considerable excitement.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

PACIFIC RURAL PRESS.

A first-class 16-page Agricultural Home Journal, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Subscription, \$4 a year.

DEWEY & CO., Publishers, No. 224 Sansome street, SAN FRANCISCO.

A GOOD PAPER.—THE MINING AND SCIENTIFIC PRESS has entered its 30th volume. It grows better as the years roll, and is, without exception, the best paper published for California miners and artisans. If such papers were more generally circulated to the exclusion of the sensation trash of the cities, the State would be the gainer in wealth, morals and general intelligence. —*Triumphant Independent.*

PATENTS & INVENTIONS

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C., Feb. 23, 1875.

FOR WEEK ENDING FEB. 9, 1875.

BATH-TUB ATTACHMENT.—Thomas D. Woolsey, S. F., Cal.

VELOCIPEDE.—Walter Knight, San Andreas, Cal.

CARRIAGE SPRING.—William S. Higgins, Oroville, Cal.

QUICKSILVER FURNACE.—C. A. Luckhart, S. F., Cal.

STEAM ENOINE.—William Wilcox, S. F., Cal.

RE-ISSUE.

BROOM MACHINE.—Henry Anderson, S. F., Cal., and James F. Houghton, Sacramento, Cal.

"The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

To Patent Attorneys, Contractors and Inventors.

WASHINGTON, D. C. January 1st, 1875.

I have carefully prepared a complete digest of U. S. patented Paving and Roofing Compositions, up to January 1st, 1875, in which is given the name of patentee, number and date of patent, ingredients, and (where given in the specification) the proportions of ingredients. Also, all of English Patented Paving Compositions up to January 1st, 1874, amounting in all to over six hundred patents, a complete state of the art to date. It is my intention to publish this work at an early day in book form, and should you wish to subscribe should address

L. W. SINSABAUGH, Assistant Examiner, Room 21, Patent Office, Washington, D. C.

VALUABLE STANDARD WORKS.

NYSTROM'S MECHANICS.
Pocket-Book of Mechanics and Engineering. Containing a Manual of Facts and Connection of Practice and Theory. By JOHN W. NYSTROM, C. E. Seventh edition. Revised and greatly enlarged by the addition of valuable original matter. FULLY ILLUSTRATED. 16mo. Pocket-Book form. Gilt edges. 50.
Nothing seems to be wanting which an engineer needs to find in his pocket-book. The tables are more than ordinarily complete. —*Electric Engineering and Architecture.*

TABLES OF MINERALS.
For the Determination of Minerals by their Physical Properties. Translated from the German of F. LEHMAN. Enlarged and furnished with a Set of Mineral Formulas, a Column of Specific Gravities, and one of the Characteristic Blowpipe Reactions. By PERCIVAL FLAHERTY, Jr., A. M., Member of the American Philosophical Society, etc. 12mo. Roan paper \$2.00.
We have here an exceedingly useful and compendious guide for explorers, who frequently have to pronounce on substances in situ, where no laboratory is at hand. The eminent author gives many new lights on classification, and his aim has been throughout to render the science of mineralogy as clear and accessible as its complicated nature will permit. The translator's work has been done faithfully and intelligently. —*Scientific American.*
For sale by Booksellers generally, or will be sent by mail postpaid on receipt of the price by

B. LIPPINCOTT & CO., Publishers,
715 and 717 Market Street, Philadelphia.

DAVID WOERNER,

COOPER,
104 and 112 Spqr St., San Francisco.
Casks, Tanks, Tubes, Pipes, Beer Barrels, etc., Manufactured at Short Notice and LOW RATES.
COPPER FOR CASKS, etc., TANKS, etc. Steamed and Dried if required.
cow-bp.

& P. N. HANNA,
IMPORTERS AND DEALERS IN

WOODBERRY COTTON DUCK.
36, 40, 42 and 45-inch Wide Duck; 8, 10, 12, and 15 lbs. Duck.

Canvas, Ravens and Drills; Roofing, Sheathing and Boiler Felt.

Ce Bags, Tents and Hose
Made to Order.

308 and 310 DAVIS STREET, SAN FRANCISCO, CAL.

FRANCIS SMITH & CO.,

MANUFACTURERS OF

Hydraulic Pipe,

AND
ARTESIAN WELL PIPE.

By the Latest Improved Machinery, we can make it an object to

Minning & Water Companies

OR
WATER WORKS,

To Contract with us for

SHEET-IRON PIPE.

Sizes Made and all Work Guaranteed.

130 Beale Street, SAN FRANCISCO.

W. BREDEMAYER,

MINING,

Consulting & Civil Engineer

AND U. S. MINERAL SURVEYOR.

Salt Lake, U. T.

Working Plans and Estimates for Mines and Improvements are furnished; will superintend the establishment of Concentration of Ores a Specialty.

For the Humboldt Company, Manufacturers of and Concentrating Machinery.

Banking and Financial.

Gold, Legal Tenders, Exchange, Etc.

(Corrected Weekly by CHARLES SUTRO & Co.)

SAN FRANCISCO, THURSDAY, Feb. 25, 1875.

HAMILTON, O. ST. LOUIS, Mo.

Hamilton Traction Engine.

OUR TRACTION ENGINE

Is no mere novelty or uncertain experiment, but is well designed, well constructed and thoroughly practical in all its operations. It is strong and substantial in all its parts, reliable and durable in action, and capable of any service for which the best of such Engines are adapted.

In its design and construction we have taken as models the best of the English engines of this class, and with modifications and improvements suggested by an experience in the construction and operation of Portable Engines, and a knowledge of the uses that will be required of them, and the conditions to which they will be subjected in this country. We thereby advertise that we are prepared to furnish a ROAD AND FIELD LOCOMOTIVE better adapted for such service and in many respects superior to any thing yet produced in that line.

For full description, prices, &c. of these or any other machinery in our line we invite parties wishing to purchase such machinery, to call and see or address us at our place of business in

ENGINES.

FOR

Steam Pumps

AND

Hot or Cold

Water Pumps

OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. **ENGINEERS, TRY IT.** For sale in any quantity by

TREADWELL & CO.'S

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM POWER COMPANY.)

We would call particular attention to the graceful design and simple mechanism of this Engine Boiler, the form in not only pleasing to the eye, but is also, the most secure and durable. The boiler is of the upright type, and is made of the best material, and is of the most perfect style, with internal fire box, and is of the most perfect workmanship, and are all tested to 150 pounds per inch. The heating surface and area of grates are in excess of the quantities usually allowed for this same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers are capable of being increased to 200 pounds per inch. The Engine is not fastened to or upon the boiler, and is therefore not affected by expansion, nor are the bearings over-heated by conduction, or the heat from the boiler. The fly-wheel being at the base secures perfect steadiness under the high speed which is necessary for economy of fuel. All parts are easily accessible—a great advantage. In comparison with the horizontal type, the upright boiler and engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety and economy. For printing offices, laundries, tanneries, ranches, small repair or machine shops, or for hoisting, wherever a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

Hoadley's
PORTABLE Engines
Sole Agents
TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine.

Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

TREADWELL & CO., San Francisco.

DUNBAR'S WONDERFUL DISCOVERY.

BETHESDA MINERAL SPRING WATER,
Of Waukesha, Wisconsin.

We claim Bethesda to be a specific in all cases of Diabetes Inflammation of the Kidneys, Inflammation of the Neck of the Bladder and Urethra, Inflammation of the Bladder, Dropsy, Gouty Swellings, Stoppage of Urine, Albuminuria, Ropy or Cloudy Urine, Brick Dust Deposit; Thick, Morbid, Bilious and Dark Appearing Urine, with Bone Dust Deposits; Burning Sensation with Sharp Pains when voiding Urine; Hemorrhage of the Kidneys, Pain in the Kidneys and Loins, Torpid Liver, Indigestion, Calculus, and Female Weakness.

There is no remedial agent known to man that can cure the foregoing diseases as effectually as Bethesda Water. This fact has been demonstrated wherever the water has been used according to directions, which can be had at the General Agents' by application to them. The water is sweet and pleasant to the taste. It can be drunk at all hours. Why should any one suffer while this Water is so easily obtained?

Number 10.

Hydraulic Mining in California. No. 15.

Mechanical Appliances.

Sluice boxes are the highways upon which hydraulic mining is carried on, and their greater or less efficiency has an influence upon this business like that of the establishment of railroads or common wagon roads upon general commerce.

Just as, by the cheapening of carriage, rail roads open coal fields, grain producing regions, etc., to the markets of the world and to a brisk commerce, where common wagon roads would hardly sustain a weak home trade, so well adapted sluice boxes will render inferior gravel deposits "paying institutions," while, *per contra*, rich gravel deposits, without proper facilities for the placing of sluice boxes, are worked at a loss.

The great requirement is sufficient grade, and a careful survey should always be made before the sluices are put in place, so that the existing fall or grade can be harnessed to the best advantage for the establishment of under-currents, drops, grizzlies, etc.

Hydraulic mines are worked with as little grade as three inches and as high as nine inches per 12 feet. In the first case abundant and cheap water generally makes up in some degree for the want of grade; in the second case a very high grade must make up for the limited supply of water.

Taking the above cited cases as the extremes, we may say that six inches per 12 feet can safely be established as the normal grade, though many important and prosperous mines are worked with four and a half and five inches per 12 feet.

The establishment of under-currents and drops must be kept in mind when the grade for the sluice boxes is laid out, and it is advisable to establish a number of under-currents on a long line of sluice boxes, even at the sacrifice of some grade. For instance, sluice boxes, with five inches grade per 12 feet, and with a number of under-currents, are preferable to sluice boxes of six inches grade and without the latter.

These facts must impress once more upon the mind of the miner the vital importance of sufficient fall for the working of a hydraulic mine, as such a favorable condition not only insures: First, sluice boxes over a high grade, and, therefore, able to carry immense quantities of gravel, etc.; Second, under currents, or large flat boxes, from 10 to 20 feet wide and from 30 to 50 feet long, provided through their whole extent with riffles, to catch gold or amalgam; Third, a grizzly, or an iron grating, placed in such position as to throw down an embankment or precipice large rocks which have been carried in the sluice boxes, and permit the smaller rocks and gravel to fall through the grating into a continuation of sluice boxes; but admits also any additional improvement, such as undoubtedly the future has in store for hydraulic mining.

The size of the sluice boxes must necessarily depend on the work they will have to perform, and may vary from four feet in width to six feet.

Supposing that a tunnel has opened the mine for work, of dimensions large enough to admit of sluice boxes six feet in width, and from 36 inches to 40 inches high, a grade or route will have to be prepared outside of the tunnel to receive two lines of sluice-boxes of the same width and height. Both these lines of sluice boxes must be connected with the boxes placed in the tunnel, and provided with strong gates, so as to cut off this connection at will. This arrangement permits the use of the sluice boxes outside of the tunnel alternately, and the "clean up" of one line of boxes without interruption of the work in the mine. However, when the boxes in the tunnel are cleaned up, the washing in the mine must stop till this is done and till the blocks or riffles are replaced. A day is generally sufficient for this work, since the tunnels, with a few exceptions, are short,

compared with the outside line of sluices, and since, moreover, the pavement, or riffles, in the tunnel sluice consist of blocks or sets of scantlings, which are far more easily removed and replaced than the stone pavement, which usually forms the bottom of the outside sluices.

After the grading is done, according to the fall at disposal, sills are laid across the track four feet apart. These sills ought to be four by six inches, and, for a double sluice, about 15 feet long, so as to project on each side of the flume or sluice, to receive posts and braces. The posts are made of four by five inch scantlings, and either 36 or 40 inches long, according to the height of the sides of the sluices. The braces are made of one and a half

H. H. OAKES' PATENT QUICKSILVER STRAINER.

by six inch lumber, and the sides and bottom of the sluice of one and a half inch plank. A piece of board eight inches wide, nailed from post to post flush with the inside of the sluice, not only gives strength to the whole structure, but may also serve as a gangway.

of the quicksilver by means of a sponge before using the quicksilver for amalgamating the next charge in the pans. This sponging is objectionable, as particles and globules of fine flowery quicksilver adhere to the sponge and to the hands of the operator so that the process

SECTIONAL ELEVATION OF STRAINER.

Whenever a curve occurs in the sluice, the larger bend, or outside, ought to be raised from one half inch to one inch, according to the degree of the curve. This will check the force of the current toward the outside curve and distribute the flowing matter evenly over the whole bottom of the flume, preventing the wearing of a deeper channel in the pavement on the outside curve.

The pavement of the sluices should be made of hard, flat stone; schist-rock or mica slate is excellent for the purpose. These stones must be placed edgewise, with a gentle slant from their base down the stream, forming a uniform thickness of 10 or 12 inches.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

WINNEMUCCA claims the distinction of being the only place in the State of Nevada that ships bullion from the ores of the district, barley raised in the adjacent valleys, flour made from wheat grown in those valleys, and beef and wool from the herds and flocks which fatten on the extensive pasturage which surrounds it.

The California Borax company are putting up another furnace at the Sulphur Bank mine in Lake county.

An Improved Quicksilver Strainer.

The invention which is illustrated by the accompanying engravings, is intended to do away with all handling of mercury after it has been strained from amalgam, and to obtain it clear, bright and ready for the next charge in the pans immediately on its being strained from the amalgam sack. Heretofore, the quicksilver when strained from the amalgam sack was received in a tub, together with dirty water, fine pulp and greasy matter, and these impurities were removed from the surface

A false bottom, *F*, the upper surface of which inclines toward the orifice, *C*, is placed in the bottom of the tub, *A*, so as to carry the quicksilver to the orifice and direct into the spout. It also serves to take the place of quicksilver and keeps as small a quantity idle in the tub as possible.

Before using the strainer it is necessary to fill the bottom of the tub with one dipperful of clean quicksilver, sufficient to cover the slot or orifice *C*. The quicksilver may then be drawn off from the end of the settler and allowed to drain itself through the sack, which should be made of light ducking so as to obviate the necessity of squeezing the sack as is usually done, and which is always attended with some loss of quicksilver. The straining may be assisted by means of a wooden staff to press down the amalgam in the sack. As soon as the quicksilver rises to the height of one inch in the center of the tub, it will flow over and under the filtering riffles and pass out at the end of the spout *B*, into a tub half filled with clean water, which is placed to receive the strained quicksilver. The quicksilver will flow out of the spout clean, bright and perfectly free from dirt and greasy matter. In the tub will be found dirty water, together with a blue soapy mud and fine particles of floured quicksilver. The strainer may be cleaned at the end of a month, the dirty contents emptied into a tub, the water strained off and the residue dried in the sun. As it dries globules of mercury will amalgamate to a certain extent so that they may be strained off. The residue or blue mass remaining is found to contain 54 per cent. of mercury which can be restored by retorting.

When the strainer is at work the cover, *H*, of the spout *B* is kept closed in order to prevent dirt from falling into the riffles. The machine is not to be moved except for the purpose of cleaning it. The amalgamator should be careful to keep the orifice or passages clear when the machine is at work and this can be done with a suitable pick, *G*.

The advantages claimed by the inventor of this strainer are as follows: 1st, That it requires no handling or sponging the surface of the quicksilver, thus saving the cost usually attending such operation.

2d, That it saves time and labor, as the quicksilver is ready cleaned for the next charge in the pans immediately on its passing from the strainer.

3d, That the quicksilver is clean, bright and free from all mud, greasy matter or blue mass.

4th, That the quicksilver being clean and lively, better amalgamation takes place in the pans, and the ores can be worked to a higher per centage, which after repeated experiments is found to be from one to four per cent., according to the grade of ore worked.

5th, That a large proportion of blue mass or fine flowy quicksilver is saved from passing away with the tailings, and which can be restored by retorting.

6th, It will also be found advantageous to pass all retorted quicksilver through the strainer before using it for amalgamation, to clean it from all dirt and greasy matter that may have passed off the amalgam in retorting.

The machine is the invention of Mr. H. H. Oakes, of Mineral Hill, Elko county, Nevada. We made reference to the strainer in September, 1874, before the patent was obtained. At that time Mr. Oakes informed us that after running quicksilver through the strainer at his mill for two weeks, he cleaned up and found nine pounds of very good floured quicksilver, of a bluish color. This was dried in the sun and on being properly manipulated, eight pounds of quicksilver were obtained. The remaining pound was a heavy kind of blue mud familiar to most millmen. The State Assayer analyzed this pound of blue stuff and it was found to contain fifty-four per cent of quicksilver. This machine can be made cheap enough to be within the reach of any miner, and will do for an arrastra as well as a 60-stamp mill, being an independent appliance.

A company of Vallejo capitalists are now mining for chrome on Oathay's ranch in Coon valley.

CORRESPONDENCE.

Solano County Mines—The St. John.

ENRONS PRESS:—Yes, it is a fact, that the Oat Hills of Solano have a wealth of quicksilver hidden beneath the soil, and in some places not so perfectly hidden but that the wayfaring man may often see its outcrop or its float. A short visit at the St. John's quicksilver mine a few days since confirmed me in the belief that the bright, nimble metal, named after the swift messenger of the god's, exists in paying quantities in this as well as in the neighboring counties of Napa, Lake and Sonoma.

Through the kindness of the Superintendent, Mr. John Neate, and his clerk, Mr. Moran, I was favored with a few facts and items. The St. John mines are situated five miles from Vallejo, at an elevation of twelve hundred feet above tide water. The communication to railroad or steamer is by excellent wagon road, and the whole distance from San Francisco only thirty-five miles.

The mines are prospected (as it cannot yet be said worked) by twelve different tunnels, in different parts of their location, and all of them in ore. Now, also running a main drain and working tunnel five and a half feet bottom, four feet eight inches at top and seven and one half feet high, perfectly timbered with sawed lumber. This tunnel, a fair specimen of good workmanship, is now in one thousand feet, but has not reached the lode. The various necessary buildings so far erected show evidence of an economic principle of procedure, very worthy of imitation in other mining companies. Yet, in the erection of their reduction works, there seems to be no sacrifice of efficiency for any seeming temporary economy. They use the Neate furnace invented by the Superintendent, who has filed caveat for patent, and will, no doubt, furnish you a proper description of the same in short time, as I could do it no justice in the limits of this letter. The small model now working has a capacity of six tons per day and gives perfect satisfaction. The fuel used is coke, charged with the ore, forty pounds of coke being ample for a ton of ore; thus making the fuel expense not over twenty-five cents per ton of ore. The greatest yearly yield of the mine has been 1,700 flasks (76½ lbs. each). The highest per month 425 flasks.

The greatest depth of shaft 125 feet perpendicular. One incline has a length of 225 feet. The north part of the mine shows a clay slate, and the south sand stone and quartzite. On the dump 500 tons ore and 250 tons *tierras* or fine ore. At present only working about 60 men, but when running all parts of the mine will require 80 or 90 men. Pay their hands in cash and they trade where they choose, no goods or liquors being sold on or near the mines, the latter a feature worthy of the highest commendation, as promotive of the best interests of all parties at or interested in the success of the enterprise.

Other mines are being located and opened in the vicinity for several miles around. About three miles from Vallejo Mr. C. Carrington has run a prospect tunnel (on his own farm) 200 feet into very fine mineral prospect, both for mercury and more precious metals. A few years may open up vast fields for mining industries and science, right here in the midst of the cow counties. C.

Vallejo, Feb. 25, 1875.

Australian Colonies—American Patents.

ENRONS PRESS:—As is frequently the case that persons coming to or traveling between these colonies use the name of the capital cities instead of the name of the respective colonies I think it desirable to make one or two trite remarks in addition to those contained in my former letter. First, Melbourne is the capital of Victoria; Sydney is the capital of New South Wales; Wellington, of New Zealand; Adelaide, of South Australia; Brisbane, of Queensland and Hobart Town, of Tasmania. In each of these cases the capital is by far the most populous and important city with the exception of Wellington, which has an ancient and formidable rival in Auckland, and Hobart Town which is left in the lurch by Launceston. I have been told by a recent emigrant from your city that people were apt to laugh at him if he told them that Melbourne was as large and as well built as it, yet I believe it is quite true; indeed my informant says that Melbourne is much the more substantially built of the two, inasmuch as the old wooden erections of the former days have, to a very great extent, disappeared before the more substantial brick and stone. Its population too, including the suburbs, amounts to nearly 200,000. As a rule its streets are straight and wide, which, for some some 6, 7, or 8 miles round about it, in every direction are the residences of most of its population, the better class, of course, living at the greater distances, railways, cars and omni-

buses being the means of communication for travelers.

Those residing in the other colonies say that we in Victoria are more after the American pattern, than they are, meaning, I believe, that there is more bueite and more of the go-ahead-ism, which is commonly attributed to your countrymen than in any of the other colonies. One British literary genius said that we had any amount of "blow" about us and perhaps in this respect we are more like you; I leave you to judge. One gentleman, however, who had resided amongst you for nearly twenty years, told me that he found Melbourne a comparatively slow place, that there was not that tremendous strain to get ahead that there was in San Francisco, and that he thought it was much easier to make money here than there.

I have been a little surprised, however, about one thing in connection with your inventive geniuses, and that is that they don't make more frequent use of the patent laws of these colonies. It is true that by reason of the interdependency of each colony it becomes a somewhat expensive thing to patent an invention in all of them, but still in some cases it would pay, and in others it would answer to patent in two or three of the principal ones. An efficient reaper and binder would pay to patent in all of the colonies, so would an invention for preserving raw meat, or for benefitting those engaged in wool growing, whilst any really good invention which would beneficially affect the gold mining industries might be advantageously protected in some three or four of them.

A Victorian colonist recently introduced Mr. Dana's sheep and cattle tags; patented it in all of the colonies, and is likely to do well out of it. Some six months before him another gentleman introduced an earth excavator from America which was far superior to anything we had here. This also was patented for the colonies, and promises to be very remunerative. So also with the Wheeler amalgamating pans, known here as "Brown & Mansfield's," and so also with many other inventions, which I cannot just now remember. Ten times as many British inventions are patented in the colonies as American ones, and yet it is notorious that the faculty is not nearly so largely developed in them as in your countrymen.

As your space is valuable, and this letter has already reached an inordinate length, I will conclude by expressing a hope that Australians and Californians will soon learn to understand and appreciate each other, and the wants and resources of their several countries, better than they do now. Yours, etc., E. W.

Mining in Montana.

ENRONS PRESS:—We are about completely snowed in. The weather so far has been extremely cold. The great body of snow which has fallen, however, will be of immense value to the mining interests. Times are rather dull at present, but the majority of our people are of good cheer, expecting a bright future, and anticipation is certainly a source of great relief. A new impetus was given to quartz mining by the new law. Those that believe in digging to find a mine, can now go to work and know, should they discover one, whether it is their own or not.

We have several serious drawbacks still—want of sure and cheap means of transportation is the greatest; want of competent machinery and competent men to run the same. There is no question about there being good ore and plenty of it, but mine owners have very exalted ideas as to the worth of their ores, and are loath to sell at a price that would justify purchasers to buy and ship to Europe. There is plenty of ore that is not high grade enough to ship at all, if there was the proper works here to work these low grade ores, or even concentrators. The bullion product would soon be large, as nothing now but exceedingly rich ore will pay to work. The shipping season is very short, a large amount of ore shipped last fall being scattered along down the river, and cannot be removed till spring.

There is a great deal of talk about concentrators, mills and furnaces that are going to be put up. Several one-horse arrangements of each kind have already been put up, but succeeded in making a signal failure. All acknowledge that there is silver and gold enough per ton to pay if it could be saved, and proper tests show this to be the fact.

I will now give you a few items from this place and vicinity. The McDaniel company at Red mountain, eight miles distant, are doing considerable work on their lodes this winter. They have several lodes near together, which show exceedingly well on the surface and as far down as they have gone. Among the number is the National Bank, Sallie Bell and Wanderer. About 150 tons are on the dumps. Average per ton of first class ore, silver, \$75; lead, 80 per cent.; second class, silver, \$60; lead, 50 per cent.

The National mining company at Unionville are working a full force of men. Mill constantly running, working about thirty-five tons per day. Their splendid new tramway from mine to mill is nearly finished. The company will soon put to work four Burleigh drills lately arrived.

The Columbia company on the Park are driving a new tunnel. Superintendent Tatern says

he is going for it deep. The company last summer purchased all the Park lode as far as discovered, paying the different owners twenty thousand dollars.

The Harvey mill at the Park is running on rock from the Caroline lode discovered last summer about seven hundred feet south of the Park, it is owned by Harvey, McNeil and Hall. Harvey and McNeil have relocated the Fannie Hill and commenced work, in the old tunnel run by Jim Witlatch. Rock from the Caroline so far has paid very well. The results of the crushing from the Fannie Hill is not yet made known.

The old Whitlatch mill is idle. Judge Turnley's mill is no more. Quite a number of small seams of quartz are being worked, but don't amount to much. SEABROW.

Unionville, Montana, Feb. 9th.

Printing and Block Making.

New Manufacturing Enterprises for California.

ENRONS PRESS:—Some time ago, in one of the San Francisco papers, I noticed an article on "Oil-Cloth Printing," and that the blocks were made here. The incident recalls the printing days of the long ago, when the calicos and shawls were all printed by hand, requiring a large number of skilled mechanics to cut the patterns on blocks, and a seven years' apprenticeship to learn the business; a few small figures were engraved on copper rollers and printed by machinery. The engraving part was also accomplished by hand, requiring a steady hand and bright eye, and few really attained the distinction of being good workmen. Designers were another class engaged at print works, designing new patterns and preparing those accepted for the cutter and engraver. Skilled mechanics engaged at the above occupations received compensation remunerative for services, which in time established traditions, compelling owners of factories to comply with terms which at this late day seem to have been very unreasonable. My own experience leads me to the conclusion that nothing but disaster follows sooner or later all compulsory measures adopted between those who hire help and the hired. Printing by hand and block cutting are almost things of the past, and soon will not be known outside of the pages of history. When in its glory no happier people existed. Good wages were obtained, and as freely spent, and it is with a sigh we part from the long ago, when calico printing by hand was the light which brightened many a fireside. With the fall of hand printing, block cutting also fell. A remnant of the old glory still finds employment in house paper establishments and oilcloth carpet works. But as the business is a dying one few will care to learn the trade. The present skilled workmen will carry with them the secrets of the past, and machinery remain master of the situation.

Engraving

Is now performed by girls and boys. Acids and etching serving as the steady hand and engraver. Calicos and delaines are now printed with a speed and accuracy truly astonishing to behold; and so is house paper, but the house paper pattern has still to be cut on rollers, by hand, giving employment to the block makers of the past.

As oilcloth printing has been established in San Francisco, why should paper printing not follow? If one can be successfully followed, so might the other, also. If no other inducement, the large freight bills of themselves would give a large profit. If calicos are ever printed in California, those engaged will reap a rich reward from the same cause.

Delaines

Would be a profitable investment—cotton and wool supplied at home, and a good market for the goods when finished. Skilled workmen could be easily obtained if capitalists would only inaugurate the movement, giving employment to those who are fitted for such occupation, and retaining capital at home instead of enriching France, England, or Rhode Island. JOHN TAYLOR.

Mt. Pleasant, Jan. 25, 1875.

ASBESTOS.—Robert Stewart, R. Hipkins and Philip Leiby, of this county, recently located claims on an asbestos lode or deposit, about four miles east of Copperopolis, in Calaveras county. The discovery was originally made by Mr. Leiby, several years ago, while prospecting for copper, and not, perhaps, being familiar with the mineral, nothing was done with the discovery. We learn the lode or vein of asbestos is about three feet in thickness, with a smaller vein running parallel with the main one. These veins appear to have gone as deep as the shaft was sunk—60 feet—and how much deeper they may continue as a matter of course is unknown. We have several large pieces from the mine in the office which looks very well. The fibers are very fine, and the mass a very pure white. The deposit seems to be extensive, and a very large supply can be furnished from the mine. This we think is the largest discovery of this mineral yet made in the State.—*Amador Ledger*.

Tests of the Haskin's Engine.

An eight horse-power (so rated) semi-portable engine, built by the Haskin's Machine Company, of Fitchburg, has recently been pumping an average of 4,000 gallons of water per minute from 15 to 20 feet high, with a total consumption of about 1,200 pounds of coal every 24 hours. The work alleged to have been accomplished is so remarkable that we give the details, which are furnished by a correspondent of the *Technologist*. Different engines of this class may be seen in this city at Parke & Laoy, No. 310 California street.

"The boiler is of the common vertical tubular type, and contains about 120 square feet of heating surface. The smoke-stack 18 feet high, and the exhaust passes through the feed water heater into the smokestack.

"The engine is of the vertical or inverted cylinder style. Cylinder 6½ inches diameter, 7 inches stroke—with Davis' patent piston valves and case—the peculiar construction of which case amounts almost to a steam jacket for the cylinder; common eccentric valve motion; valves adjusted so that the steam follows about two-thirds of the stroke; Waters' governor, the belt of which was thrown off, leaving the valve wide open, so that the engine was regulated by the throttle; feed pump worked by an eccentric or engine shaft; coil heater, the feed water passing through a tube enclosed in a vertical cylinder through which the exhaust steam passes on its way to the smokestack.

"The pump was one of Perry's 8-inch horizontal centrifugal, and was used to drain a ditch which was about a mile long. The water was run out of a box ditch about 500 feet long—and the quantity was measured as accurately as possible, the results recorded being the means of very many trials, as the contractors were paid for the number of gallons discharged, and were paid by these measurements.

"The fuel was a mixture of Cumberland and Cannel coals, and is all the coal that was bought for the engine and charged to it, the weights being taken from the weigher's tickets, and the gross average amount being 1,461 lbs. per day.

"The steam varies from 100 to 125 lbs. pressure per square inch; engine running from 200 to 360 revolutions per minute, as the occasion demanded, and after running two months night and day steadily, without repairs of any kind, was reported apparently in as good order as when first started.

"Using Moleworth's formula for pumping engines, we find 4,000 gallons of water per minute \times 60 minutes \times 24 hours \times 17½ feet—a fair average—that the result equals 100,800,000 gallons raised one foot high in 24 hours. Dividing by 4,752,000, we find that it requires 21.2-horse power to do the work. Allowing 10 per cent for waste, ashes, etc., (which were not weighed) we have 1,467—146=1,321 pounds of coal for 24 hours, and average of 54.7 pounds per hour—so that they obtained a horse-power with the expenditure of very little more than 2.5 pounds of coal per hour. Even charging all the coal, with no allowance for refuse, the result is under 3 pounds of coal per horse power per hour—which results very few first-class engines of large calibre can or do excel.

"This report is verified by the contractor, the foreman, and the civil engineer in charge of the work, and for this class of work presents the best results of which we have a reliable record—the vertical boiler being regarded as anything but the most economical form. This shows conclusively what can be done by good proportions, good workmanship and good management, and we think it worthy of being recorded."

Mining at Grass Valley.

The present winter has been a favorable one for quartz mining, and we believe all the mines of that character have been and are doing well. There has been considerable misgivings in regard to hydraulic mining. There has considerable water fall during the winter—the average amount, we believe; but the heft of it came at the time of the heavy storm, and went in a flood down to the lower country. But little snow has been deposited in the mountains, all of which has been regarded as unfavorable to a successful mining season by most people. In a conversation with J. E. Brown, agent of the South Yuba Canal Co., we learn that he considers the season a very good one; in fact, that it will equal last year, when a much greater rainfall was had. At that time the months of February and March were cold, and flumes and ditches were frozen up, and but little mining was done. This winter has been more favorable, and the company has been selling as much water part of the time as they do in summer. Mr. Brown thinks the time gained in this manner will more than equal the length of time which would be shortened in consequence of a less rainfall. The time that the company have to let in water to their ditches from their reservoirs usually averages from ten to twenty-five days. That is to say, a dry winter makes the mining season so much shorter. As more than that time has been gained the present winter on account of the weather being favorable for work, Mr. Brown thinks the present season will be a very good one. The agricultural interests never looked better; so, take it all together, the year will be a prosperous one for the State at large.—*Foothill Tidings*.

MECHANICAL PROGRESS.

Rivets on Iron Ships—Something New.

Wm. Palliser writes: I know with absolute certainty that the rivets with which the plates of iron ships are fastened together are utterly worthless when subjected to an impulsive strain, such as would be caused by a heavy mass like a boat being dashed with violence against the side of an iron ship. Under a strain of this nature rivet-heads become as brittle as glass. I have previously pointed out this fact, but the answer has been that no proof of the failure of rivet-heads in ships at sea has hitherto been obtained. I will mention one experiment which occurred at Shoeburyness some years ago in proof of my contention. On this occasion a peculiar structure was built up with cast iron solid cylinders, laid horizontally in tiers upon each other. The face of that structure was covered with an iron plate similar to those used in ship-building. The iron face was fastened to a frame by means of a row of rivets round its edges, just as the plates of a ship are riveted together. At the first shot, the whole of the rivets, to the number of many dozens, were broken, just like a row of postage stamps; and I may state, that I felt quite certain beforehand that such would be the case, judging by the way that rivets had invariably snapped in other structures under similar circumstances. Now the strain on those rivets, although impulsive, was comparatively not very violent, and had the plate been fastened with short screw bolts, reduced in the shank to the lesser diameter of the screwed part, not a single bolt would have been broken. Could it be proved that, owing to the breakage of rivets, the plates of the *La Platte* separated and let in the sea, and, further, that the rivets were broken by the blows struck by the boats against her sides, it would follow that all iron ships are liable to a similar danger, and the hitherto unexplained loss at sea of many iron ships would be at once accounted for. Several years elapsed before I succeeded in establishing to the satisfaction of others the cause of the breaking of ordinary armor bolts, and I am certain that the same tendency to snap exists in a far higher degree in the ordinary rivet.

DISTRIBUTION OF STEAM.—M. A. Van Wacy-saberoth has invented a new arrangement for preventing the dangerous irregularities which occur in steam cylinders; he adopts two or more escapes and sets of slides, placed on different sides of the cylinder, and so arranged that they are all connected with the extremity of the cylinder by the same passage. He admits the steam and governs its introduction directly by the regulator according to the work to be done. With this object the arbor of the levers which command the valve slides forms part of a sliding sector which is furnished with clickwork, rendering it at any determined moment independent of the slides and transmission rods. When this occurs, the steam-way, which was open, closes instantaneously, and the inlet, being unoppressed, the steam acts by expansion in the cylinder until the piston has reached the end of its stroke. The discharge port then opens, and the steam passes into another cylinder, into the condenser, or into the air, according to the circumstances of the case.

BELLS AND AOR.—A fiddle improves by age and use; a piano does not, neither does a bell. There is, perhaps, a slight improvement for the first few years, but afterwards the quality deteriorates. Metal we know, is altered by repeated and long continued hammering. Thump a piece of iron, and you change the quality of its magnetism; the shock of the waves modifies the magnetism of an iron ship; and some of the music is knocked out of a bell by long continued use of the clapper. A peculiar effect is noticed in the bell of Crippletoe church when it strikes twelve. The first two or three strokes are distinct and clear, then a discord begins, which accumulates with every stroke, until with the eleventh and twelfth a complete double sound is produced.—*Chamber's Journal.*

A RAILROAD ON ICE.—A Duluth paper proposes a railroad on ice from Duluth to the Sault—the whole length of lake Superior. It claims that all that is necessary is to spike the rails to the ice, without grading, filling, excavating, ballasting, or ties. The track, it says, could be taken up every spring and stowed away. The road would be about 400 miles long, and a dead level. The ice lasts till April; a thick enough to sustain a train of cars; the freight cars could be transferred to the ice without reloading, and the rails could either be spiked to the ice or they could be fastened in a frame and laid on the ice without spikes.

IRON BRIDGES.—The first iron bridge ever built was constructed at the Colebrookdale Iron works, England, by Abraham Darby, and was erected across the Severn, near Colebrookdale, in 1778. It is of hundred and twenty feet span, and although it has been in constant use from that day to this, it is in as good condition now as ninety-seven years ago. Thome Gregory served his apprenticeship as a draughtsman and a pattern maker, and when his time was up he was engaged by Darby as foreman of his shop, and the iron bridge of Colebrookdale is one of Gregory's productions.

LEATHER BOARD FOR ROOF COVERING.—The application of board made of leather parings for covering roofs is steadily on the increase, says an exchange, especially since it has been found practicable to impart to the material the required durability, imperviousness and its *sine qua non*, a great resistance against the constantly changing influences of the atmosphere. Only by changing the mode of manufacture these properties could have been secured. According to the German edition of *Engineering*, the board formerly used for covering in roofs was a spongy, easily compressed mass, which received a single coat of tar, and which had the great fault of softening, and consequently losing its consistency in damp atmosphere. This has lately been superseded by a product manufactured by P. Desfenx and others of fibrous matters, possessing a great substance, such as leather, and which are in the process of manufacture impregnated with an oleaginous chemical composition, imparting to the material when cut into sheets like paper and dried, the appearance of real leather. This system of covering in roofs offers considerable advantages especially from an economical point of view. The new roofing board is said to be very light, and consequently, as no other material, suitable for slight constructions.

RELATIVE STRENGTH OF SOLID AND HOLLOW IRON COLUMNS.—The quantity of iron in solid columns of strength and height necessary for carrying the doors of ordinary warehouses and workshops is fully 50 per cent. greater than that which would suffice to cast hollow columns of similar strength and height. Thus a solid column of cast iron, four inches in diameter, weighing 40 pounds per lineal foot, has only the same amount of strength as a hollow column five inches in external diameter and 9.16 inches in thickness, weighing 29 pounds per lineal foot, when the height is nine feet; and a solid column 12 feet in height, seven inches in diameter, weighing 122.4 pounds per lineal foot, is only of equal strength with a hollow column of similar height, having an external diameter of nine inches, a thickness of one inch, and weighing 80 pounds per lineal foot. The late Eaton Hodgkinson ascertained that within certain limits the strength of columns is as the 3-6th power of the diameter in inches, and universally as the 1-7th power of the length or height of the column. The formulae for calculating the strength of the columns of cast iron, both solid and hollow, and of any proportion of length to diameter, is given in the second part of Tredgold's "Practical Essay on the Strength of Cast Iron and other Metals."

STEEL BRONZE.—The Vienna correspondent of the *Times* furnishes the following notice of Major-General Uchatius' "steel bronze." Above 1,000 shots have been fired with increased charges from a gun made of this bronze composition without the least deterioration being visible. The grooves, which are the first to suffer with bronze guns, are as perfect as they were on the first day. Hitherto the experiments have been made with the common projectile in use with the present bronze gun. The experiments are to be continued with closely adjusted projectiles, a battery will be formed in the arsenal to test the range and precision as well as the adaptability of the new composition for breech-loaders. If found equal in all these respects to steel guns, the steel bronze guns will have the advantage of being lighter, and consequently superior for handling and maneuvering in heavy ground, which will be a great source of saving; for it is calculated that the present bronze gun might be transformed at about one-fourth of the cost which a change to steel guns would entail. It would, too, be much cheaper, for the worn-out guns might be recast, instead, as with steel guns, of being sold for old iron.

ELEVATED RAILROADS.—In the report recently made by the American Society of Civil Engineers, upon the various plans recommended for rapid transit in New York, underground railroads are regarded as out of the question, and the plan of elevated railroads is favored. Even the imperfect road of this character already built on Greenwich street has done something to shorten the distance out of the city, and to bring its northern and southern extremes nearer together. But it is considered a very imperfect and unsafe affair. The Committee of Engineers demonstrate by figures that such a road can be built so as to be safe, meet all the wants of rapid transit, and return a fair interest on the cost. The Committee have the matter still under discussion, and wealthy citizens are said to be subscribing liberally, to demonstrate the practicability of such an enterprise.

DANGEROUS BOILERS.—The Hartford Steam Boiler Inspection and Insurance Company have issued their annual report, comprising a pamphlet of twenty pages, from which we glean the following: Inspection visits, during the year, 14,368; inspections made, 29,200; defects discovered, 14,256—about one for every two boilers examined; furnaces out of shape, 602; fractured plates, 1,127; burned plates, 867; blistered plates, 2,368; deposit of sediment and incrustation and scale, 4,816; water gauges defective, 548; defective blow out, 267; overloaded and defective safety-valves, 343; pressure gauges defective, 1,809; boilers without gauges, 714; deficiency of water, 78; broken braces and stay and insufficient bracing, 685; boiler condemned as unfit to run, 163—most of them worn out.

SCIENTIFIC PROGRESS.

Science vs. Spiritism.

At a meeting of the New York County Medical Society, January 12, 1875, Dr. J. C. Peters remarked at length upon the trickery of so-called spiritual manifestations and mind-reading, and in conclusion presented the following resolution:

Resolved, That a Committee of five be appointed by the Chair, to consider, and at their convenience report upon, the following questions:

First—Is the state or condition of mind known generally as the mesmeric state, a reality or a deception?

Second—If it is a real physiological state, what are the conditions necessary to its production, and what are the phenomena attending it?

Third—Is it a state to which one mind can submit another, or does it depend upon some conditions voluntarily submitted to by the individual?

Fourth—Is it possible, while in this so-called mesmeric trance, or at any other time, or in any other condition known to man in his mundane experience, for one person to divine what is passing in the mind of another, except through the medium of signs?

Fifth—Is there any such faculty known to our race as perceiving by some mysterious second-sight what is transpiring in places far beyond the reach of ordinary human vision, or what is written on paper when an opaque object lies between it and the person attempting to read?

Sixth—Is there any evidence that the well-known law of gravitation is ever overcome by a force hitherto unrecognized by scientists?

The resolution was adopted and the following gentlemen named as the Committee: Dr. Ellsworth Elliott, Dr. J. C. Peters, Dr. Fordyce Barker, Dr. Austin Flint, Sr.; Dr. A. B. Crosby.

Artificial Production of Precious Stones.

An address on clay and its economic application was delivered by Prof. T. C. Archer on the occasion of the inaugural meeting of the fifty-fourth session of the Royal Scottish Society of Arts at Edinburgh.

The president commenced by a reference to alumina and its various alloys. One of the greatest discoveries of the present age, he said, was the obtaining of the oxide of aluminum in a pure crystalline state. It has long been known that the precious stones were composed of oxide of alumina colored by other metallic oxides; and it was a very fair inference that if they could succeed in melting the oxide alumina, there was nothing in the world to prevent the manufacture of emeralds, sapphires, rubies, etc. This had actually been accomplished by a Parisian chemist, and the artificial gems were of the same hardness and density as, and chemically identical with the real stones. Beautiful stones were exhibited, after which the professor proceeded to explain the composition of the various kinds of clay, and to detail the uses to which they had been put from the earliest periods of history.

He spoke also of the restoration of the lost art of encaustic and mural tile making, and described how those beautiful ceramic articles were manufactured, and the manner in which they were salt-glazed. The introduction of this kind of ware into the building of houses would, he said, add much to the beauty of our architecture—the more especially as the atmosphere had no effect upon their coloring, as in the case of serpentine and even granite. He next touched on the application of salt-glazing clay to sanitary appliances and gas retorts, and concluded by a reference to the improvements made of late years in the construction of pottery-kilns, which had the effect of saving fuel to the extent of one-third.

INTERESTING EXPERIMENT.—The combustibility of iron is a well known fact, but a Berlin experimenter has demonstrated the phenomenon in a manner peculiarly his own. He takes a straight bar magnet of some power and sprinkles iron filings on one of its poles. These filings arrange themselves in accordance with the lines of magnetic force, and however closely they may appear to be placed, of course no two of the metallic filaments are parallel, and consequently a certain portion of air is enclosed, as in a metallic sponge. The flame of any ordinary spirit lamp or gas burner readily ignites the finely divided iron, and it continues to burn most brilliantly for a considerable length of time, the combustion being apparently as natural and easy as that of any ordinary substance. If the experimenter with this operation stands on a slight elevation and waves the magnet to and fro while burning, a magnificent rain of fire is said to be produced.

THE GREENWICH MERIDIAN.—The French Academy of Sciences, it is announced, are about to consider the propriety of adopting the meridian at Greenwich, which is already recognized by the other nations of the Continent, in lieu of that of Paris. The meridian would touch the French soil at Tronville, and, in the event of the Government sanctioning the change, a column would be erected on the spot.

Earth to Earth.

Science appears to be opposed to the ordinary way of committing dust to dust. The relation of the dead to sanitary conditions has been again brought up by a proposal of Mr. Seymour Haden, to bury in coffins of a light, permeable material, such as wickerwork, open at the top, and filled in with any fragrant plants that may be in season. A coffin such as Mr. Haden suggests, while satisfying every sanitary, would, he thinks, at the same time satisfy every sentimental requirement—"a layer of ferns or mosses for a bed, a bundle of sweet herbs for a pillow, and as much as it would still contain after the body had been placed in it, of any aromatic or flowering plant for a coverlet—such a covering, in short, as, while it protected the body from the pressure of the earth as effectually as the stoutest oak, would yet not prevent its resolution." Yet a good deal would depend on the nature of the soil in which interment took place. Some soils do not possess sufficient depurative power, while others, such as light, gravelly ones, would allow too free a passage to the fetid and noxious gases which arise in the first stages of decomposition. Further, it is almost certain that disease germs are not destroyed, at all events rapidly destroyed, by burial, as was shown when the people of Murchampton perished in great numbers from an epidemic which originated in the application of the rich black earth of its churchyard as a garden compost. Still, where the ground is suitable there could be no reasonable objection to the adoption of this proposal, and a covering of quicklime might be added where necessary. Cremation is undoubtedly the best and most effective mode of disposing of the bodies of the dead in the interests of the living, but there is an apparently insurmountable prejudice to its use, although it is the method which the early Tenth-century settlers—regarding their descent from whom Englishmen are so fond of boasting—brought with them from the wastes and forests of the Continent.—*Iron Age.*

SPONTANEOUS COMBUSTION OF CHARCOAL.—The woods generally used for the production of charcoal are those of the cornel tree, the willow and the alder. These are all well suited to the purpose, but the cornel tree is used for the best kinds of sporting powder. The wood is converted into charcoal by heating in cylinders of iron. When the charcoal is drawn out of the cylinders, it is placed in other iron cooling vessels, fitted with air-tight doors. It is left in these for a space of about fourteen hours, at the end of which it is generally cool. It is then taken to the mill to be ground, and afterwards to be mixed with the other ingredients to make cannon powder. But a curious phenomenon has been noticed frequently at this stage, and which might indeed be fraught with danger, if the operations should be unduly accelerated. The powdered charcoal frequently becomes hot, and has been known to fire spontaneously the day after the grinding. This is explained, no doubt, by the fact that the charcoal absorbs large quantities of oxygen into its pores by capillary attraction, and that the condensation of the gas in the interior is the cause of the heat, and the non-conducting power of the charcoal the cause of its spontaneous firing. The quantity of gas absorbed is increased by the light to which the original temperature had been raised. The absorption also of the gas is much more rapid in the powdered condition than in that of sticks.

"COOGIA'S COMET" A MASS OF METEORS.—During the recent appearance of Coggia's comet, Mr. Norman Lockyer, the English astronomer, made some valuable scientific discoveries. Every night, while the comet was visible he was on his watch tower, using the most powerful telescope in England; he mapped its march and photographed its every phase; he resolved its fan-shaped nucleus into millions of shooting meteors; and he experimented on the large number of meteorites in the British museum—meteorites that have fallen in every part of Europe—and found that when heated up to a certain point their spectroscopic signs were exactly those of the comet. Mr. Lockyer is coming to this country shortly, to confer with our scientific men, whom he accredited with the greatest achievements in the recent transit of Venus.

ECLIPSE OF THE SUN.—Astronomers, who are yet in the midst of their labors, working out the grand results of their observations as related to the transit of Venus, will have another interesting occasion presented for astronomical research on the 5th of April, when there will be a total eclipse of the sun. The course of the central line of this eclipse will be principally a sea track, in which the best opportunities for marking the phenomena attending it will be during the passage from the Nicobar Islands, in the bay of Bengal, to Siam. The King of Siam has heartily invited British and other astronomers to make the observations within his dominions, and volunteered to extend them every facility and hospitality.

COMPLIMENTARY.—An eminent English astronomer, Lockyer, said to M. D. Conway, an American journalist in London, in speaking of the results of the late transit observations: "Whatever was done was accomplished by the Americans. They seem to be the only people now that take hold of such things in the right way."

General News Items.

CHOKED TO DEATH.—A singular and very sad accident occurred near Belmont on Friday of last week. A child of Mr. Newhall, a little boy only two years and a half old, was out searching for eggs. As he was absent for some time his brother was sent to look for him, and was horrified to find the child in the stable dead, with his neck tightly jammed between two of the upright rails of a manger. The inference is that the child in his search climbed upon the manger, and missing his footing in reaching out, fell with his neck between two of these bars, which converge toward each other at the base, and was choked to death. The feelings of the bereaved mother were indescribable. Mr. Newhall is a brother of H. M. Newhall, the well known San Francisco auctioneer, and is also an esteemed member of the San Mateo Grange.

FRIGHTFUL ACCIDENT IN A CHURCH.—A frightful accident occurred at St. Andrew's Catholic church, in New York, on Thursday evening, of last week: While Rev. Father Carroll was preaching and about half through the sermon, the ceiling over the right gallery was crushed in by the fall of the brick wall of an adjoining building. The church was quite crowded, and a stampede followed. The firemen and police soon arrived and succeeded in allaying the excitement. Four persons were crushed to death during the rush for the doors. Their bodies were at the foot of the gallery stairs. Three others were also found dead and 71 wounded.

SUDDEN DEATH OF A NOTED CLARINET PLAYER.—On Sunday evening last, James R. Kendall, an old and popular clarinet player of the California theatre orchestra, dropped instantly dead in the music room of the theatre. As he entered the music room he hung up his hat and overcoat, and saying "Good evening, gentlemen," to those about him, wheeled about and fell to the floor a corpse. Physicians were summoned and several rushed in, but Kendall was beyond aid—he died instantly as he fell.

POSTAL CHANGES FOR CALIFORNIA.—Post Offices Established.—At Cinnabar, San Benito; Geo. W. Chick, postmaster. At Fountain Springs, Tulare county; Moses Davis, postmaster. Postmasters appointed: J. F. Sperry, at Big Trees, Calaveras county; W. S. Whitaker, at San Simeon, San Luis Obispo county.

ENOUGH TO KEEP HIM FROM WORK.—King Alfonso's allowance has been fixed at \$8,000,000 reals—that is \$3,500,000 which will, no doubt, prove a real comfort to him, and ought to procure him food, lodging and clothes of a superior kind.

OPPOSITION TO THE HAWAIIAN TREATY.—From the expression of prominent Senators, it is believed that the Hawaiian reciprocity treaty will meet with much opposition when it comes before the Senate for action, and there is a strong probability of its rejection.

LOCOMOTIVE WORKS DESTROYED BY FIRE.—The Cliff Locomotive works at Clifton, Penn., were burned on Saturday morning of last week, with the valuable machinery, three new engines, etc. Loss over \$500,000; insured for \$200,000, chiefly in New York.

RESIGNATION OF GOVERNOR BOOTH.—Newton Booth filed with the Secretary of State his resignation of the office of Governor, and left for Washington on the overland train of Sunday.

Mining Stocks.

There is no change to record in the aspect of the mining market. Everything continues dull with few sales and low prices. Some expectation of a rise seems to be entertained by the sanguine, who contend that present prices are altogether too low for the merits of the mines. This may be the case with some of the bonanza mines, but there is no doubt even in the low tide in the market, that a good many stocks are selling at more than they are worth. There is a certain class which the brokers know as wild cat in which there is hardly any probability of striking ore enough ever to pay a dividend. Nevertheless, these mines are dealt in simply for speculation, and they answer every purpose for that. The general supposition is that the "Cometock deal" is over for the season, and some hopes are entertained of a rise in Idaho or Ely stocks by outsiders. This, however, can only be determined by the "inside" whoever they may be. At present there are no special indications that it will take place. Reports from the bonanza mines continue good, but they do not seem to affect the market as such reports used to do. How long the present depression will continue, it is impossible, of course, to say.

THE Oro mining company, Sierra county, are preparing to erect a 15-stamp mill.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

EAST YELLOW JACKET M. Co. March 2.—Location: Storey county, Nevada. Directors—Robert Sherwood, C. L. Weller, C. S. Neal, H. W. Fortuna and H. C. Kibbe

while a score or more lesser veins are operated with success. Several rich strikes have been recently made, notably by Briggs & Fisher, on the North Star, Lee Ham & Co., on the old Mitchell lead, Bastian & Bryor, near town, and George Chick & Co., on the North Fork slope. Besides these, numerous soft granita leads are being worked and paying well. The custom mills are kept running night and day, upon rock taken from these various veins. The coming spring promises to be a busy season in that district, as capital has taken hold of two of the leading mines while experts have been examining other ledges.

THE LONE STAR MINE.—One day last week we paid a visit to the Lone Star, located three miles northwest of West Point. We had heard frequent mention made of the mine but were not prepared to see so good a development as is exhibited. The vein has nearly a north and south course and starts from the edge of the North Fork of the Mokelumne river, and runs along one of the ridges of the river hills. Tunnels No. three and four on the Lone Star ledge have each cut an extremely large chute of ore; in the neighborhood of 40 feet in width by 100 feet in length with a perpendicular distance between the two tunnels of 150 feet. We saw several prospects of this chute, made from rock taken at random, which would yield \$80 to \$100 a ton. The average width of the two veins, excepting this chute, is Lone Star three feet and the Reed and Hillery two feet. There are now on the dumps about 700 tons of ore, some of it very rich while a portion being surface rock is of a poorer quality. It is calculated that the rock taken as a whole will mill \$20 to \$25 a ton.

EL DORADO COUNTY.

MINING DEVELOPMENT.—Mountain Democrat, Feb. 27: Within the city limits or in the vicinity of Placerville there is an immense amount of quartz. In some cases it presents itself in ledges of enormous proportions; in others it appears in the shape of seams and stringers which experienced and well informed miners are confident come together at greater or less distances from the surface. From time to time there has been more or less of rich gold bearing quartz taken from nearly every one of these ledges, seams and stringers. But although this is a familiar fact, and although ours is one of the oldest mining camps in the State, it is yet a marvellous fact that in this whole region not a single ledge has ever been systematically and thoroughly prospected. It is perfectly manifest that nothing would so greatly and speedily benefit our section as would the development of a permanently paying quartz mine. If one ledge was sunk upon to a depth of say 800, 600, or 500 feet, and a body of ore developed which would pay even moderately for milling, it is beyond a peradventure that within a brief period there would be dozens and scores of similar enterprises set on foot and ours would at once become one of the liveliest quartz mining regions in the State. To the property holders of Placerville and vicinity we submit this proposition: That they all unite in forming a joint stock company for quartz and prospecting, each taking such amount of stock as he can conveniently carry without hampering himself; then, after a general and free conference, at a spot he settled upon which is believed to offer best promise of success, and then let us go to work—hit or miss—and see something that lies more than 200 or 300 feet below the surface.

FRESNO COUNTY.

MINING.—Fresno Exploitor, Feb. 27: We are informed that Floyd, Dodds & Co. have been making some very good quartz from their mine, situated about four miles below Crook's ranch in the Fresno river. They have just finished rushing about eight tons of ore and got over fifty ounces of gold, or about \$75 per ton from the rock. They have about ten tons of ore which they estimate will yield fully \$500 per ton. Such a mine as that, if extensive, is better than Consolidated Virginia.

NEVADA COUNTY.

ORE REDUCTION WORKS.—Nevada Transcript, Feb. 27: R. M. Fryer & Co., of New York, are erecting works near the race track, for the purpose of reducing all kinds of auriferous ores. The rock will be worked without crushing and everything works as experiments heretofore prove it will, the company will be able to work any kind of mineral, so as to secure results equal to the ordinary process of assaying. It will, in short, be assay works on a large scale. It is expected to work rock as closely as any assayer can do it. The proprietors intend to enlarge the works as the demand requires. They have perfect confidence that the process will prove a success, and they will be ready for operation in a few days. Mr. Fryer has visited different points on the coast, and thinks this the most favorable of all. We hope success will crown their efforts.

GREAT ENTERPRISE.—Foothill Tidings, Feb. 27: One of the most extensive mining enterprises in California is that of the North Bloomfield Gravel mining company, which owns some hundreds of acres of deep auriferous gravel deposits in this county. Hamilton Smith, Jr., superintendent and engineer, in a report dated the 25th ult., says the total expenditure has been \$1,979,760, including \$498,000 for the main tunnel, nearly 8,000 feet long, \$1,031,000 for ditches, reservoirs and water rights. An additional expenditure of \$50,000 will increase the storage capacity of the reservoirs to 6,500,000 gallons. The company has been working for years, but has not yet fairly commenced washing out the gold. The ground is known to

be rich and they expect to take out enough to compensate them well for the cost, delay and risk of their enterprise.

PLACER COUNTY.

GREEN MINE.—Placer Argus, February 27: An extensive building has been erected adjoining the old hoisting work to accommodate a battery of ten stamps, complete separating and amalgamating works are connected therewith, and though the works are not very extensive no better quartz mill can be found in this region. An extensive reservoir has been built, in which the water pumped from the mine, is preserved for use in the mill. The works started up on Monday last, but during the week, little more has been done than to adjust the machinery, and get things to running smoothly. The mine is now yielding an abundance of good ore to keep the mill running up to its full capacity, and we may soon look for a favorable report.

THE CRATER MINE.—At the Crater mine, the St. Patrick company is driving business with an evident determination to do something. The 212-ft level is being driven from No. 2 shaft, in good ore. From shaft No. 1, the workmen are driving the 312-ft level, and have an 18-inch ledge of good milling ore. The 360-ft level from the same shaft is in a two foot ledge, and is yielding milling ore. The work of driving the 440-ft level of same shaft is just fairly begun. The rock is improving, and the foreman expects to strike the pay-chute of the 360-ft level, in a short time. The St. Patrick mill is running steadily, and the last clean-up from Crater ore, yielded \$30 to the ton. The mine is not at present yielding sufficient ore to keep the mill going, but as soon as the lower levels are fully opened out, the supply will be ample.

THE BOOTH MINE.—The main shaft has now reached a depth of 153 ft, and the ledge now shows fully four feet in width, of high grade ore, at this point the second level will be started, and rich developments may be looked for. The appearance of the mine is of the most encouraging character, and fully meets the expectations of all interested.

PLUMAS COUNTY.

GOON QUARTZ.—Plumas National, February 20: We are indebted to Mr. H. B. Bransford, of Taylorville, for a splendid specimen of quartz from the newly discovered ledge belonging to the Taylor Bros., at Crescent. The rock is full of free gold, and the beauty of it is that it is proving to be an extensive ledge. Two tunnels are now being run, and one of them is now in some seventy feet, the other just commenced. The first shows a ledge averaging eighteen inches in width, and at the end of the tunnel it appears to be increasing in size. All the rock shows free gold in such quantities as to prove that it will pay, when crushed, at an enormous figure. One objection to it is that the ledge does not "pitch" fast enough, but if it holds out anything like that portion already developed, it will be "good enough for anybody." We certainly hope it will, and that Crescent may once more regain the life and business which it had in years gone by.

SONOMA COUNTY.

MINING ITEMS.—Russian River Flag, February 25: Eleven flasks of quicksilver came down from the Missouri retorts last Saturday, the product of ore from the Georgia. Nine and a half tons of Georgia ore was reduced in the Missouri retorts and yielded eighteen flasks and fifty pounds.

Work continues on the Lincoln silver mine. Superintendent Gilman informs us that the shaft he is sinking on the ledge is now down 80 ft. After going 20 ft deeper he will drift each way on the vein. The owners of this mine are very sanguine in their belief that it will prove profitable property. Numerous assays have shown the rock to contain silver and gold in paying quantities.

The Home company (incorporated), whose mine is on the summit above the Annie Belcher, have struck a body of black oxide ore in their shaft, similar to that in the Socrates.

The Edith company (incorporated) are preparing to put up a furnace. Their mine is on Pine Mountain, above the Georgis. They have plenty of good furnace ore in sight.

The Rattlesnake company started their furnace again about ten days ago. It is working more satisfactorily, but they will soon build a Knox & Osborne furnace.

Rich ore has been struck in the northwestern end of the Sonoma. There is enough in sight to run the furnace a year. The superintendent has been getting out ore and building a road to it. The furnace will soon be fired up.

EXCELSIOR MINE.—By invitation of Mr. Sroufe, President of the Excelsior Quicksilver mining company, we paid the mines and works of that company a visit a few days since. Their location is in Inyo district, at the mouth of Sausal creek, on the road from Healdsburg, to Pine Flat and equidistant from the two points named, or eight miles north from Healdsburg. There are two mines belonging to the company—the Excelsior and the Chapman—and containing fifteen hundred feet each. At the Chapman, five tunnels and shafts have been commenced on as many different points along the croppings. Neither one, however, has yet been prosecuted to any considerable extent, though the ore has been struck in each, and in one at least, in considerable quantity and of very good quality. At the Excelsior, which is located on the right or opposite slope of the mountain, six tunnels and shafts have been commenced, and a railway three hundred feet in length constructed down the mountain side for running ore from the mouth of the tunnel down to the road below. On this claim

also, we were told, ore has been struck in each instance. Notwithstanding that the company have a working force of near eighty men employed, a sufficient length of time has not yet transpired since the commencement of work to pronounce the mines fairly opened. The indications for a really valuable mine, however, are exceedingly encouraging, and we hazard but little in predicting that ere many months the Excelsior will rank high in the stock market. The furnace of the company, which is a most substantial looking affair, is of the Winterburn pattern and capable of running through some fifteen tons of rock every twenty-four hours.

TRINITY.

RICH CINNABAR.—Trinity Journal Feb. 27: Cañon Creek bids fair to rival if not excel the Cinnabar district in the production of the ore for which the latter was named. There is an exhibition at the Union hotel 16 pounds of as rich cinnabar as we have ever seen, taken from near the surface on the Mountain Laurel mine, near Cañon creek, where three stringers have been found. A tunnel is being run by the Mountain Laurel company, which it is expected will strike these stringers in about fifty feet, and large developments are anticipated. We shall not be surprised at any time to hear of rich discoveries of cinnabar in other sections of the county.

ANOTHER DISCOVERY.—A ledge of ore-bearing rock has been discovered near the Bush ranch, twelve miles from Hyampome. Many opinions have been given as to what kind of ore the rock contains, it being variously claimed as lead, tin and silver. Whatever it is, it is immensely rich. As yet, none of the rock has been brought to town, and no tests made. By another issue we hope to report the discovery within our county limits of a rival Comstock.

PAYING WELL.—Henry Engel has been quietly working his quartz ledge on East Fork for several years past, during which time it has paid regularly, and for the amount of work and the manner in which it has been done, paid well. A late clean-up from 13 tons of rock, worked with an arrastra, averaged \$57.50 to the ton. Becoming tired of this primitive mode of working, Mr. Engel started for San Francisco this week, intending to make arrangements for the erection of a mill. He certainly has a good thing, and one which will pay large dividends with proper machinery for working the ore.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill News, February 25: Daily yield, 460 tons of ore. The ore slopes throughout the entire mine are looking splendid and are yielding the usual amount of rich ore. Enlarging the drifts and laying the double car tracks on the 1500-ft level are about completed. The mills are all running steadily and are doing good work. The C. and C. shaft is down 221 ft, the sinking making rapid headway.

CALIFORNIA.—The north drift on the 1550-ft level has been driven ahead 13 ft during the past week, the face still in the richest possible character of ore, the whole drift being in fact a magnificent chamber of ore, literally bespangled with silver. On the 1500-ft level, east cross-cut No. 1 on the south line, has been stopped for the present, the face still in rich ore, and a drift north started to connect with cross-cut No. 2 to obtain a better ventilation. This drift is passing through a splendid character of ore, and is now in a distance of 30 ft. Cross-cut No. 2 east, on the same level, is also being driven rapidly ahead, the face still in rich ore. Cross-cut No. 3 east is also in fine ore, and has been advanced 20 ft during the past week. Cross-cut No. 4 on the 1500-ft level is in 67 ft, the face still in porphyry.

OPHIR.—There is little or no change in any of the ore breasts on either the 1366 or 1465-ft levels. The north winze, on the 1465-ft level, is down 125 ft, the bottom still in fine ore. The face of the east cross-cut, on the California line, on the 1366-ft level, is also looking much more favorable for a continuation of the ore body to the eastward. The north drift, on the 1700-ft level, is being driven steadily ahead toward the Mexican line, encountering frequent small kidneys of fine ore.

BELOHER.—The ore breasts on all the different levels are looking well and yielding the usual amount of good ore. Daily yield, 450 tons of ore. The three winzes being sunk below the 1400-ft level, have all been stopped for the present for the purpose of timbering. The bottom of all the winzes are still in fine ore. As soon as they are thoroughly timbered their sinking will be resumed.

CROWN POINT.—Daily yield, 400 tons of ore, keeping the mill steadily running. There is nothing new to report of the ore producing sections of the mine. The main east drift on the 1600-ft level is still pushed vigorously ahead, with every prospect of soon striking the main ore vein. The main incline is down to the 1700-ft station.

ORIGINAL GOLD HILL.—The prospects in this mine have been growing better and better of late, and especially since our last week's report. The raise above the south drift at the 340-ft level, which we then made mention of, has progressed upward to the height of 27 feet, following the east wall of the ledge, and in excellent milling ore all the way. From the track floor up 15 feet it was white ore, fine and easily worked, but above that point it changed gradually to the regular red ore peculiar to the Comstock upper levels, or to the general depth of 300 feet. The face of the

raise is now in this red ore, and from personal inspection of it this morning we consider that it has every appearance of developing into a large solid body of most excellent ore. Assays from the track floor up have averaged from \$50 to \$400 to the ton. The width of their new ore development is not as yet ascertained, of course, and cannot be until cross cutting is done.

CHOLLAR-POPOSI.—Sinking the main incline below the 1250-ft level has been resumed. The 1250-ft station is completed and a drift started to cut and prospect the ore vein in that portion of the mine. The main south drift on the 1100-ft level is still being pressed ahead without change of value to relate.

SAVAGE.—The main incline has about reached the point at which the 2200-ft station is to be opened. The north drift on the 2000-ft level is making good progress, with no change worthy of note. The foundations for the new incline machinery are completed, and the machinery is now being placed in position ready for use.

BULLION.—The north drift on the 1700-ft level of the Imperial is still driven rapidly ahead, much better progress being made during the past month than at any time previous. The quartz in the face of the drift continues of a fine, favorable character, and in a short time a cross-cut will be started east to prospect the ore vein, when there seems hardly a doubt but that a paying mine will be developed.

SIERRA NEVADA.—The old prospecting drifts on the 700-ft level of this shaft are being rapidly cleaned out, and put in condition for future operations. The ore vein at this point, and that part of it lying between the old and new shafts on the 700-ft level, is as yet almost entirely unprospected, and some excellent results may well be looked for when cross-cutting in that portion of the mine shall have been commenced.

NIAGARA.—The shaft is now thoroughly timbered, and is in the finest possible working condition. Sinking has been resumed on the ore body struck in the bottom of the shaft before the work was suspended. The ore is of high grade, and is steadily increasing in width as a greater depth is attained. Spots of black sulphure ore, carrying a large proportion of gold, are frequently encountered.

KNOTCHEROCKER.—A heavy clay wall is met with in the face of the drifts west, at both the 600 and 700-ft levels, and drifting both north and south is commenced at both of the levels mentioned. This is supposed to be the east or paying wall of the main ledges, and not advisable to cut through at present, on account of the probability of encountering a heavy flow of water. When the powerful new machinery and increased pumping facilities of the company are made available, which will be in about a week or two, cross-cuts will be made through the clay wall and into the full merits of the ledge itself.

LANY BRYAN.—The ore body developed in the southeast cross-cut on the 180-ft level, is opening out finely. It has been prospected to the east wall of the ledge, and is 39 feet in width, and will mill from \$30 to \$40 per ton. Some rich developments may soon be looked for, as the whole ore vein is undoubtedly improving in quality as a greater depth is attained.

JULIA.—Sinking the shaft is making fair progress, notwithstanding the extreme hardness of the rock penetrated. The shaft is to be supplied in a very short time with Burleigh drills driven by compressed air, which will greatly expedite that portion of the work.

IMPERIAL-EMPIRE.—Driving the south drift on the 2000-ft level is making fair progress, the quartz in the face gradually assuming a more flattering prospect for an ore development.

IOWA.—Preparations for the erection of new and powerful hoisting machinery for prospecting the mine in good shape, are rapidly approaching completion.

LEO.—Driving the main tunnel is making good progress the face still in very promising ledge material, carrying seams of fine ore. The ledge continues well defined and strong, being about five feet in width.

MEXICAN.—The north drift on the 1465-ft level, is still driven rapidly ahead, encountering frequent spots and streaks of fine ore. It is the intention to soon start a cross-cut to the eastward to cut and determine the true value of the ore vein at that point.

WELLS FARGO.—Sinking is resumed at the bottom of the shaft, with the new hoisting works in full operation. A station will be opened next week for the first drift to the ledge.

GLORY CONS.—The main west drift on the 400-ft level is still driven vigorously ahead, the quartz in the face looking quite favorable.

JACOB LITTLE CONS.—A strong force of men are now employed in the development of this mine. The several drifts and cross-cuts on the tunnel level are looking more and more favorable for the development of a paying mine.

AMAZON.—New shaft down 40 ft, in good sinking ground. It is well timbered throughout. A number of small feeders of quartz have been encountered which look very favorable.

WOONVILLE.—The new ore body in the north drift on the 300-ft level is looking finely. Sinking the new shaft is making good progress.

PICTOR.—Air pipes are being introduced into the tunnel, and drifting ahead will be resumed shortly, as soon as the requisite supply of good air can be furnished.

SENATOR.—The drift north on the 400-ft level has shown much improvement during the past week. Selected samples of the ore give large assay results.

The King-Bird.

The king-bird, or "Field Martin," as it is sometimes called in the Southern States, remains at the North during the spring and summer; and, although men destroy it, Mr. Audubon declares its occasional destruction of a honey-bee, and larceny of a few raspberries and figs, to be the only mischievous acts it commits, while, he alleges, its beneficial deeds are countless, insects chiefly caught upon the wing being its accustomed food. It appears in Louisiana about the middle of March, and continues until the middle of September. Further northward, over the entire country, it comes later and disappears earlier. For a few days after its arrival, it seems fatigued and doleful, and remains perfectly silent; but its sharp, tremulous cry is soon heard over the fields and along the skirts of the woods. It seldom enters the forests, but is fond of orchards, large fields of clover, the neighborhood of rivers, and the gardens close to the houses of planters. As soon as incubation has commenced, the male, full of ardor, evinces the most daring courage, and gallantly drives off every intruder. Perched on a twig in view of his mate, he seems to direct every thought and action to cherish and protect her; and, though he seldom meddles with small birds, yet often flies to their rescue, when he spies a crow, a vulture, an eagle, or a martin making any approach, spreading his wings to the air, and pressing toward the dangerous foe, he commences his attack with fury. Mounting above the enemy, he sounds the charge, somewhat like a watchman's rattle, repeatedly plunging upon the back of his powerful antagonist, and endeavoring to secure a hold. In this manner, he harasses him with continued blows, and follows him at times for a mile, when, the fugitive having sought refuge in the forest, with quivering wings and trilling notes, the little bird returns exultant to his nest. Audubon says, that the martin alone, of all aerial enemies, inspires him with fear; that, although this bird frequently aids him in protecting his nest and watching over the farm-yard, it sometimes attacks him, and, excelling him in quickness and power of flight, eludes his more powerful blows, and in some rare instances, destroys him. Few hawks venture to approach a farm-yard while the king-bird is near; and even the cat, tormented by his attempts to peck on all sides, retreats from before him to the house.

Agricultural Matters at the University.

After attending the meetings of the Academy of Sciences at the University of California on Washington's birthday, we took a stroll through the grounds to see what was being done in the agricultural department. A portion of the grounds, dedicated to practical agriculture, has been thoroughly plowed, graded and otherwise prepared by deep trenching and working over for nursery purposes. Work in the agricultural department, as far as out-door agricultural work is concerned, was commenced on the 1st of June, 1874.

Two propagating houses have been constructed and were ready for use in the latter part of August, 1874, and a commodious and convenient building for work rooms, with suitable benches for potting and handling plants, constructed, with storage arrangements for prepared soil, pots, tools, etc., and a suitable office for gardener, and sleeping room for watchman.

The propagating houses are of the dimensions respectively of 30 by 20 feet, and 64 by 15 feet, and in the rear of the latter is a laboratory pertaining to said houses, 64 feet in length by 12 feet in width; these buildings are arranged so as to facilitate the work and so conveniently placed that the whole is easily supervised by the gardener.

The propagation of plants of economic value, as well as such species as are more particularly required for the purpose of illustrating general botany and ornamenting the grounds, in pursuance of the general plan devised by Mr. W. H. Hall, was at once commenced, and such vegetable forms as are valuable to the pomologist, and necessary to illustrate floriculture and arboriculture have already been produced in large numbers. The entire domain belonging to the University includes 200 acres, sloping to the west, a parallelogram in general shape, and presenting quite a diversified topography; its lower portion being about 200 feet above the level of San Francisco bay, and rising towards the east into hills, the summits of which are about 900 feet above the sea level. Some 40 acres are reserved for agricultural purposes and experiments, and the remainder to illustrate the principles and methods of landscape ornamentation, forestry, botany, and allied studies.

A well designed and convenient barn, 36 by 44 feet, and a story and a half in height has been built, and the principal road which traverses the farming grounds has been marked out and partly graded, to facilitate the farm work.

From advance sheets of the "Bulletin of the University of California" we learn that since the propagating houses were ready for use on the 22d of August, 10,000 plants, 20 species of Eucalyptus, 5,000 Acacias of 25 species, 200 species of native and foreign Conifers, also

numerous rare forms peculiar to Australasia, South and Central America, and elsewhere, and many species of textile, medicinal and other economic plants have been produced. We may mention 112 varieties of Roses, 13 of Azaleas, 12 of Camellias, 6 of Magnolias, for ornamental purposes.

The planting of a standard orchard, for the purpose of correcting the nomenclature of the fruits already in cultivation, and for furnishing hereafter scions and plants for distribution through the State, as well as for the introduction of new varieties to be distributed as above, has received consideration. The following have already been planted, and it is the intention to still further enlarge the list.

Varieties.	Varieties.
Apples.....141	Blackberries.....7
Siberian Crab-Apples.....14	Gooseberries.....8
Pears.....132	Currants.....8
G cherries.....82	Raspberries.....34

Quinces.....2	Rhubarb.....16
Nectarines.....15	Mulberries.....6
Grapes.....73	

They have also procured many varieties of

these eggs have done which were brought by rail from the East.

Mr. R. E. C. Stearns, Secretary of the Regents and Superintendent of the grounds, shows commendable zeal in the collection of favorable varieties of fruits and trees, and with the assistance of Mr. Ellis, the gardener, has already made marked progress in matters relating to the agricultural department. Mr. Stearns earnestly requests all interested in this department to visit and inspect the grounds, and will be happy to receive suggestions and carry them out as far as the means at disposal will permit. Considerable difficulty has been experienced with the soil, which is hardly adapted for nursery purposes, and this has given a large amount of extra work. It seems to us that very good progress has been made in this department, considering that out door work was not commenced until the first of June.

A WONDERFUL COAL DISCOVERY NEAR DAYTON, NEVADA.—Some wonderful coal discoveries have just been made in El Dorado canon, a few miles southeast of Dayton. A short time since there occurred a flood in the canon, which

THE KING-BIRDS.

oranges, lemons, limes, etc, and all the species of walnuts and chestnuts.

Among the apples are nine new Russian varieties, and the peaches include seventeen of Rivers' new seedlings.

It is not to be expected that with a local climate and soil, all the above can be successfully grown at Berkeley, but it is very probable that many of them can be successfully cultivated, and the University may be able to add more or less to the number of useful varieties now produced in the State.

The State Fish Commissioners have recently erected a propagating house, and many thousands of ova and young brook trout may be seen in the troughs. It is proposed to build dams at favorable points in the creek and its branches, for the double purpose of protecting the banks and furnishing ponds for the fish. We saw at the hatching house a somewhat unusual occurrence—namely, double fish, or rather young fish one week old, joined together in a peculiar manner. Some of these have two heads and one tail, while others are distinctly formed but are joined together something after the fashion of the Siamese twins. We are told that some of the salmon eggs taken from this State to the East, hatched out in this peculiar manner, as

swept away the tollroad leading up along its channel and tore things to pieces generally. The road being washed away, it appears that no one tried to travel through the ravine. A day or two since, however, the Virginia City coal company, whose mine is well up toward the head of the canon, sent some of their employees out to examine the road in order to see if it were possible to repair it. In traveling down the canon these men came to a place where the water had torn up and swept out the whole bed of the stream, exposing an immense bed of coal. The coal has been torn up and washed down the stream, and there remains a regular pavement of it across the canon and for a considerable distance along its course. The new district is not covered by the original location of the Virginia City coal company, but we understand some of the members of the said company, with their employees, have taken up a large scope of ground covering the recent find. As yet they have not dug through the bed to ascertain its thickness. A gentleman who returned from the canon yesterday, and who is a member of the company above mentioned, is of the opinion that the coal laid bare by the recent freshet is the outcrop of the second vein cut in their shaft.—Ter, Enterprise.

Sending Parcels by Mail.

By the operation of a late law the Postoffice Department has supplanted in a degree the express companies as carriers of small parcels. Under this law there may be sent through the mails, at the rate of two cents for every four ounces or fraction thereof, not above four pounds in weight, in addition to engravings, seed hulls, and all other articles which are not from their form and nature liable to destroy, deface, or otherwise injure the mail bag or the person of anyone engaged in the postal service. All liquids, poisons, glass, explosive materials, and obscene books were excluded. This opened the mails to the reception of a vast quantity of small packages which were to be conveyed from one part of the country to the other, and insured for such parcels prompt dispatch to the remotest part of the United States, at a charge of but one cent for each two ounces or fraction thereof.

In sending packages of this description it must be observed that the law directs that all packages must be so wrapped, with open sides or ends, that their contents may be readily and thoroughly examined by the postal clerks without despoiling their wrappers. No writing is permitted except the address of destination, and to enclose or conceal a letter, or write or print anything upon a newspaper or other matter enclosed as a merchandise package subjects the sender to prosecution and fine. If it is necessary to break or tear a wrapper, letter rates are to be collected on packages so wrapped when they are delivered.

From a New York paper of a recent date we notice that it appears by the returns of the Postoffice Department that there were sent through the mails, from fifty of the leading cities of the United States, during four weeks of December, 1874, 225,733 pounds, and that during the same time, at the New York office alone, the number of pieces was 85,054, weighing 36,905 pounds. This may be taken as a good average month's work, so that in the course of the year nearly 500,000 pounds of this class of matter will be sent from the office in that city.

The result of this patronage of the mails has been a corresponding loss to the express companies, who are now said to be endeavoring to secure the repeal of the law. Such a movement is likely to be met with warm opposition as the success of it would secure to the express companies a monopoly of the business.

The Stayton Mines.

Our readers will all remember the sale a few months ago, of the celebrated Stayton quick silver mines, in the Coast range mountains between the counties of San Benito and Merced, by the Stayton Bros., of this county. Their many friends here will also be glad to learn that they have received their money from the English company, which we understand was paid last week. The purchase price was \$200,000. This is but a just reward to the enterprise of these men, who labored with such zeal for the development of these valuable mines.

Robert Stayton is still retained as Superintendent, and the work under his personal supervision has been progressing all winter, with the most satisfactory results. One shaft of the Cold Spring lead, says the Hollister Enterprise, is down 102 feet, disclosing an immense bed of rich cinnabar. On the Pacific lead the shaft is 92 feet deep, exposing a four-foot vein of silver metal. A small furnace with less than a ton capacity has been in operation for some time, and the average yield of the ore has been ten per cent. With these reduced facilities retorting, the mine has paid all expenses including wages of twenty hands, mining implements, material, fuel, etc., and left a margin sufficient to pay one per cent, per month the sum paid for the property. Indeed, it is believed that there is metal enough in sight to dump to pay the \$200,000 without touching the unmined ore at all. From the production of this small furnace some idea can be formed of the capacity of the mines for producing wealth when the larger works of the company are put in motion.—Ex.

WATER GLASS deserves more extended household usage. Mixed with paint or whitewash gives increased durability and a fine gloss, is an excellent fire-proof cement, and when also water-proof. It is a good adhesive and a good material for mending china, glass, or wood, made into a wash is the best coating for barrels.

PATENTS are taken for every conceivable device for the use of man, and invention even goes beyond the coffin. We find a recent patent apparatus for depositing coffins in graves. An invention for filling up graves is now on order.

ENGLISH CAPITAL is seeking investment in the coal and iron lands of the Southwest States to a considerable extent, and the development of that section will probably be accomplished chiefly by those who represent foreign owners.

THE SPRINGING OF SHAFTS.—If a shaft is running, the trouble lies probably in either too small diameter of the shaft for its weight and velocity, a set of unbalanced pulleys, or unequal strain on either side by the belts.

PLATINUM.—Enormous deposits of this valuable metal are reported as having been found in the State of Morelos, mining district Tacala, Mexico.

Good Health.

How to Live Ninety Years.

"With a good appetite three times a day, delicious sleep, and not an ache or a pain in the whole body, the mind all the time fully alive to what is going on in the world, and all the time in good spirits." This is said of the late ex-Governor Throop, of New York. He retired at nine, and rose at six, taking a nap in the forenoon, and sometimes in the afternoon also, breakfast at eight, dinner at one, and tea at sundown. In suitable weather he spent a greater part of the forenoon in his garden, directing his men, and assisting them, and for a short time in the afternoon was employed in the same way. He used no spirituous liquors, but took claret wine every day at dinner.

There are three things in the above narration which, if persistently carried out in early life, would do more than all others towards giving all an enjoyable old age, viz: regularity in eating, abundant sleep, and a large daily exposure to out-door air.

Regularity in eating, either two or three times a day, with nothing whatever between meals, not an atom of anything, would almost banish dyspepsia in a single generation; as frequent eating is the cause of it in almost all cases, especially if irregular, and fast.

Abundant sleep and rest from childhood make nervous disease a rarity; to insufficiency of regular sleep, and insufficiency of rest, may well be attributed nine-tenths of all sudden deaths, and a premature wearing out before the age of sixty years. All hard workers, whether of body or brain, ought to be in bed nine hours out of the twenty-four, not that so much sleep is required, but rest, after the sleep is over; every observant reader knows how the system yearns for rest in bed after a good sleep, and it is a positive gain of energy to indulge in it.

Every hour that a man is out of doors is a positive gain of life, if not in a condition of chilliness, because no in-door air is pure; but pure air is the natural and essential food of the lungs, and the purifier of the blood, the want of which purification is the cause or attendant of every disease; while every malady is alleviated or cured by an exposure to out-door air. If city wives and daughters would average two or three hours every day in active walking in the open air, it would largely add to exemption from debility, sickness and disease, and would materially add to the domestic enjoyment and the average duration of life.

HYGIENE FOR THE AGED.—In one of his recent clinical lectures at Guy's Hospital, London, Dr. Haversham referred to the case of an old man who died simply from the shock produced by going out into the cold and fog, which though only an inconvenience to people generally, was sufficient to lead to a fatal result in one whose circulation had become enfeebled, and whose vital force had so nearly lost its power. Dr. Haversham also alluded to an instance of longevity of which he had been informed by a gentleman—the case being the latter's mother, who had died at the age of 102, and who, during the winter months, used to refuse to get up, saying that she was warm only in bed. To this uniform warm temperature the fact of her great age was doubtless owing, and Dr. Haversham urges that in prescribing for old people they should be advised to keep warm; and as they cannot eat much at a meal, they should take them more frequently. There are many of them also who wake up at about three or four o'clock in the morning, and it is a good plan for them to have some nourishment then; otherwise the interval between the night and morning meals is too long for their declining strength. The life of the aged may be considerably prolonged by care in these minutiae.

COUGHS AND BRONCHIAL AFFECTIONS.—Afflicted persons will find great relief, and in most cases a certain remedy, in the following prescription:

Carbonate ammonia, 30 grains; tincture cinchona comp., 1 oz.; syrup senna, ½ oz.; pargoric, ½ oz. Dissolve the ammonia in the syrup by aid of a mortar and then add the other ingredients.

Directions.—One teaspoonful half an hour after each meal, or take the last spoonful on retiring. Shake bottle before pouring.

It was written a number of years since by Dr. Edwards, one of the most eminent physicians of New York City. The object in taking after meals is to allow it to remain on the diseased parts, therefore do not take anything to remove the taste from the mouth. It will be put up by any druggist.

EATING BEFORE SLEEPING.—It is a common mistake to suppose that eating before sleeping is injurious. Not at all unfrequently does it happen that people are sleepless for want of food and a little taken when they first go to bed or when they thus awake sleepless, will generally be found more efficacious, and of course, infinitely less injurious than any drug in the chemist's pharmacopoeia. These are the physical remedies for sleeplessness which have the best recommendation. As for the moral one there is certainly a good deal more to be said. Perhaps the most stringent of all rules are to avoid anxiety and "don't go to bed owing anybody a grudge!" chewing the bitter end of a quarrel is a thousand fold more injurious to repose than swallowing a whole teapot of the very greenest of green tea.

ADVICE TO BATHERS.—Mr. Young, the Secretary of the Royal Humane Society, publishes the following excellent advice to bathers:

Avoid bathing within two hours after a meal. Avoid bathing when exhausted by fatigue or any other cause.

Avoid bathing when the body is cooling after perspiration; but bathe when the body is warm, provided no time is lost in getting into the water. Avoid chilling the body by sitting or standing naked on the banks or in boats after having been in the water. Avoid remaining too long in the water, but leave it immediately there is the slightest feeling of chilliness. Avoid bathing altogether in the open air, if after having been a short time in the water, there is a sense of chilliness, with numbness of the hands and feet.

The vigorous and strong may bathe early in the morning on an empty stomach; but the young and those who are weak had better bathe three hours after a meal; the best time for such is from two to three hours after breakfast.

Those who are subject to attacks of giddiness and faintness, and those who suffer from palpitation or other sense of discomfort at the heart, should not bathe without first consulting their medical adviser.

WHOOPING-COUGH REMEDY.—One of the London journals contains a statement by Dr. Berry of his successful treatment of uncomplicated whooping-cough with diluted nitric acid, in doses of from five to fifteen minims, according to age, with simple syrup, given every three or four hours, alleviated the cough and spasms, and apparently cutting short the disease. During an epidemic of disorder he prescribes this frequently and with very satisfactory results. He offers no suggestion as to the operation of the remedy, but he believes its action to be that of a tonic sedative, and antiseptic, and, at the same time its refrigerating properties are not to be lost sight of. In all the cases treated he has, of course, paid attention to the state of the digestive organs, and in such as require it he has given an aperient combined with an alterative.

TONICS FOR WOMEN.—Nothing makes a woman aged more rapidly than overwork—the reason, probably, that American women fade so soon. Sunshine, music, work and sleep are the greatest medicines for women, who need more sleep than men. Their nerves are more sensitive and they are not so strong, and exhaustion from labor or pleasure takes place sooner with them than with men. Never permit yourself to be roused out of deep sleep in the morning. In fact, one should never be awakened. The body rouses of itself when its demands are satisfied. Take a warm bath occasionally before going to bed—at least once a week. Retire as soon as you feel sleepy in the evening; don't rouse yourself and go to work. You need rest then, and will pay for the trespass on your physical nature the next day if you disobey.

Useful Information.

Comparative Tests of Building Material.

The superiority of American steels and irons to similar grades of metals of foreign production has been often asserted; and it is now proposed to definitely settle the point, which is of the utmost importance in engineering, mechanics and agriculture, by a Government commission. The suggestion comes from the American Society of Civil Engineers, who deputed a Committee to wait on the House Committee on appropriations, on January 26th, to urge the passage of a bill now before the House, which provides that the President shall appoint a commission, consisting of a representative each, from the Engineer, Ordnance, and Navy corps, the Coast Survey and four civil engineers, to serve without pay, to institute and carry out such a system of tests upon American building materials, particularly iron and steel, as would result in the adoption of a standard of strength to govern future construction.

Similar experiments have been made in Europe, and data, for the guidance of architects and for the use of local boards in framing building regulations, have been obtained. Hitherto our scientific men and artificers have had to use these results; but we hope that improved practice, comprehending the well known facts as to the excellence of American metals, will result from the appointment of the proposed commission.

A WORD OF CAUTION.—Experiments by Galley show how dangerous it is to allow greasy refuse to lie, even in small quantities, in warm places. He found that such waste dipped in boiled linseed oil, and wrung out, required, at a temperature of 170 degrees only 105 minutes at the most to take fire, and that the bulk need not be very great as a match-box full at 167 degrees took fire in one hour. With raw linseed oil it required 4 to 5 hours; with rape oil at 170 degrees over 6 hours; with castor oil at 185 degrees, over a day; with olive oil 1½ hours; and with sperm oil it would not take fire at all. The heavy coal and petroleum oils were found to retard oxidation by excluding the air. Silk waste did not take fire, but gun-powder placed in it was fired in an hour; and in cotton under similar circumstances only after 1½ hours.

Manufacture of Oatmeal.

After the outside hull and the stratum of down covering the kernel are removed, the clean grain is ground into meal; and being deprived of its tough outer covering, care must be taken lest it be reduced to powder.

The first and most expensive apparatus required is the kiln for drying or expelling the moisture from the grain until the kernel is hard and the hull stiff and rigid. The ordinary kiln is built of brick or stone, and so arranged as to distribute the heat equally under and around the drying floor. This floor consists of sheet-iron or cast-iron plates thickly perforated with funnel-shaped holes, the wide end downwards, thus allowing the heat and smoke to pass up, and preventing the oats and dust from passing or choking the holes. The roof is constructed like an inverted hopper, with a square opening at the top for ventilation, and surmounted by a cupola with latticed sides. The oats, which are spread upon the kiln floor, are constantly stirred, to dissipate the moisture and prevent the lower strata from being scorched, until the batch is sufficiently dried. In this way, from 150 to 600 bushels per day are kiln dried, according to the capacity of the kiln.

Another style of kiln is also in use. This consists of two or more perforated sheet-iron cylinders placed in the furnace one above the other, and so inclined that the oats gradually move from the higher to the lower end. The oats, after passing through the upper cylinder, are deposited into the upper end of the second, and from the lower end of the second into the upper end of the third, and so on, the number of cylinders, their length and velocity being governed by the capacity required. This is, undoubtedly, much superior to the old style of kiln, as it has a regular feed and dries the oats much more evenly and thoroughly. After the oats become cool, they are ready for shelling.

The stones best adapted for shelling are a coarse free sand-stone. The bed-stone is faced perfectly true, but the runner has a bosom of about three-sixteenths of an inch around the eye and running back to nothing at about two-thirds of its diameter. The outer stone is dressed to a true face, corresponding to the bed-stone. The faces are picked or roughened as for ordinary grinding, but have no furrows. The runner is set upon a stiff ryne, keyed to the spindle. The ryne has three or four arms which are let into open grains cut into the stone. The faces of the stone are not allowed to run very close to each other, being about a kernel's length apart. The dister and fan for removing the hulls and dust are simple and easily constructed. The grinding is sometimes done on the hulling stones, but it is generally advisable to use much smaller stones, furrowed, and having a smoother and much less grinding surface.

The apparatus for bolting and sifting is very simple in construction, being a series of inclined sieves placed one above the other. These sieves are usually made of tin or zinc, into which are punched round holes of suitable size and sufficiently far apart to allow the hulls to slide over. The meal passes through these sieves, while the bran passes over it at the lower end of each.

THE PRESENT TIMBER SUPPLY FOR EUROPE, and possibly, in the not very remote future, for the Atlantic States of America, comes, and will come, from Russia and Finland. Large quantities are obtained from Sweden and Norway, which contain extensive tracts of forest land; but the principal resource must be from the extensive forests of Russia, from which timber is now imported by Great Britain alone to the amount of several millions of pounds sterling annually. From Russia also ultimately will come the European supplies of furniture and wooden ware. The Russian market will be for many years to come an increasing one for all sorts of wood-working machinery. American manufacturers who have the eagacity to cultivate this market, and the enterprise to be among the first that enter it, can scarcely fail to build up a large and profitable trade in wood-working machinery.

A BEAUTIFUL ART.—The Japanese make a beautiful hrouze—five parts of tin, ten parts lead, and 100 parts copper—which is cast in thin sheets, upon which beautiful designs in silver is incrustated in the following manner: The plates are covered with a varnish upon which the designs are graved with a style, the plates are then plunged into a snitably prepared bath to receive a deposit of silver upon the graved lines. When a sufficient deposit has been formed on the parts from which the varnish has been scratched, the plates are placed in a muffle furnace, in which the bronze turns black and the silver remains white and brilliant, showing up beautifully by the contrast.

IMITATION OF MARBLE THAT CAN BE POLISHED.—An elegant imitation of marble is made in Dresden for architectural purposes, by impregnating sandstone with silicic acid and alumina. In Naundorf, such stones are prepared which are intensely white, transparent, and capable of taking a polish. By the introduction of suitable pigments in the impregnating mass any desired color is produced. It is stated that the cost is much less than real marble, while it resists heat better.

STEEL-BRONZE GUNS.—We hear from Vienna that considerable sensation has been produced in military circles by some brilliant trials of new Austrian guns in steel and bronze. They have proved superior to Krupp's cast-steel guns.

Domestic Economy.

How to Prepare Feathers for Use.

Make bags of coarse unbleached cloth—one to contain the geese and ducks' feathers, and the other for chickens' and turkeys' feathers. When plucking the poultry, cut off the wings first; and if not needed for dusters, strip off the feathers from the parts nearest the body, and then peel off the feathery part from the quill, but take care that no skin or flesh adheres to any of the feathers. Put the bags into a brick oven, if you are the fortunate possessor of one, and keep them there, excepting when the oven is used for baking purposes—taking them out into the wind occasionally, and beating them with a stick. When you have collected enough to fill a pillow, cut the shape you desire out of bed-ticking, and stitch it round on the wrong side with coarse, well-waxed thread, leaving a small space at the top to put in the feathers. Now lay it on a table, and run it over on the wrong side with a piece of beeswax, just warmed a little, so that it will besmear the ticking. If you cannot obtain the beeswax, common yellow soap will do as well.

If you do not wish to use the feathers either for pillows or sofa cushions, they can be put into beds that have become a little empty. The geese and duck feathers make the best beds, but the mixed feathers will do well for cushions. If any of the skin or flesh adheres to the feather, they will have a putrid odor, which may seem to be an unmountable objection to their use; but if, after a family wash is finished, the bag, tied up closely at the neck, is put into the boiler of soap and boiled a few moments, moving it about with the clothes stick, and lifting it up and down and squeezing it out a few times, and is then taken out and hung in the air, and shaken hard, for several days, when the feathers become dry they will be light and free from any bad smell; and they can now be put into the oven, and thus kept from moths and be always ready for use.—*Country Gentleman.*

FRENCH CREAM CAKE.—Beat three eggs and one cup of sugar together thoroughly; add two tablespoonfuls of cold water; stir a teaspoonful of baking powder into a cup and a half of flour; sift the flour in, stirring all the time in one direction. Bake in two thin cakes, split the cakes while hot, and fill with prepared cream in the following manner: To a pint of new milk, add two tablespoonfuls of corn-starch, one beaten egg, one-half cup of sugar; stir while cooking, and when hot put in a piece of butter the size of an egg; flavor the cream slightly with lemon, vanilla or pineapple.

HOW TO USE CHLORIDE OF LIME.—Eckstein, a technical chemist of Vienna, after comparative tests with the other disinfecting agents, recommends chloride of lime as decidedly the best for water closets, cesspools, etc., and attributes its efficacy and its rapid action in decomposing hydrogen compounds, such as ammoniacal sulphuretted hydrogen, etc. He regards as the chief objection to its general use, its unpleasant effect on the organs of respiration, and states that this can be remedied, and its action regulated, by enveloping it in a bag of parchment paper, which acts osmotically, and is decomposed slowly by it.

WHY BROWN OR RAW SUGARS ARE NOT GOOD FOR PRESERVING FRUIT.—Raw or brown sugars generally contain a certain proportion of glucose, a fermentable non-crystallisable sugar, which is a source of great trouble in fruit preserving. Sugar to be used for this purpose should be in crystals, as that form precludes the possibility of any impurity being present. Loaf-sugar may be used with advantage, as being free from the impurities mentioned, and not liable to ferment.

DOON-MATS.—Mats should be laid outside of all doors, to stop the currents of cold air that come from under them; and they should fit the doors exactly, for if they do not they are rather more ornamental than useful. The large, square mats are now seldom used, excepting in houses where large and handsome doors demand them; but the narrow mats, only twelve or eighteen inches in width, look best in limited space, and serve the requisite purpose.

ORANGES, BANANAS AND COCOANUTS.—Cut oranges through the sections into handsome slices. Place a layer in a high glass dish. Sprinkle the orange with fine sugar, and a layer of grated cocoanut; lay thin slices of banana on this, sprinkle cocoanut, then another layer of orange, sugar, cocoanut and banana until the dish is full. Place on ice for an hour before serving. From "Choice Receipts."

FURNITURE POLISH.—An excellent furniture polish is made of ten cents worth of beeswax placed in a tin cup and melted in a hot oven. Into this pour two ounces of turpentine and let it stand to cool. Apply it briskly to the furniture with a woolen rag, and give it a finishing rub with an old silk handkerchief. This polish is almost equal to a coat of varnish.

TO PRESERVE BUTTER.—Take two parts of the best common salt, one part of loaf sugar and one of saltpetre; beat them well together. To sixteen ounces of butter thoroughly cleansed from the milk, put one ounce of this composition; work it well, and put it down in earthenware jars when cold and firm. It should be kept from the air and not used for a month.

cels by Mail; The Stanton Mines, 150.

THE Virginia Enterprise states that prospect-
ing is wonderfully active at present in all direc-
tions about the city, notwithstanding the depth
of snow still remaining on the ground, and the
somewhat unsettled state of the weather. When
spring comes the hills will be alive with men,
and the clank of machinery and the scream of
steam whistles will be heard in many wild
places.

BETHESDA mineral water from Wankesha,
Wisconsin, is much used in this State. This
water, from nature's laboratories, is clear,
sparkling, and pleasant to the taste. It is
claimed to possess wonderful curative prop-
erties, and for kidney disease is a specific. For
persons who indulge in viuous and alcoholic
stimulants, the water is an invigorating drink.
It acts as a mild cathartic, which makes it in-
valuable to many persons. The agents, whose
card appears in our advertising columns, show
many testimonials to the virtue of Bethesda
water.

THE Petaluma Argus says a rich lode of
quicksilver has been discovered on the ranch
of A. P. Whitney, on the South Eel river. Nu-
merous prospectors have visited the place in
the last few days, and the ledge has been lo-
cated for nine miles in length.

THE new air shaft on the Belcher mine is
down to the 800-ft. level, and its good effects
are already being felt throughout the entire mine.
It is being thoroughly timbered, preparatory
to continuing it on down to connect with the
lower levels of the mine.

THE new or Talbot coal mines, near Seattle,
are now going forward in development. The
tunnel is now 420 feet long and still extending
day and night. There are 12 feet of coal in the
seam, with a half inch of shale or slate in the
center.

THOMAS LYONS, late Superintendent of the
Sapphire and Devil's Gate mill, has been ap-
pointed Superintendent of the Woodworth
mill, on the Carson river.

JOHN P. SHEAR has sold his interest—one-
half—in the Veith & Shear hydraulic claim on
Tunnel Ridge, Calaveras county, to his former
partner, for \$2,500.

MR. SKIDMORE tells us that while at Gold
Run the other day, the Indiana Hill cement
company washed out \$126 from one bucket full
of dirt.

Japanese Wrecks.

At the last meeting of the California Academy of Sciences, Charles Wolcott Brooks read a paper giving an account of the Japanese wrecks picked up adrift on the North Pacific, and stranded upon the different outlying islands and shores of our northwest coast, and the chain of islands extending from Hawaii toward Nippon. The paper itself was simply a record of 41 junks which had been picked up adrift or stranded from 1782 to the present time, but Mr. Brooks' conclusions were of scientific interest. His sources of knowledge are exceptionally good, as he has represented the Japanese Government in this city for 17 years, and has paid great interest to the subject. He is investigating the question of the origin of the Japanese.

Before reading his paper Mr. Brooks explained that every junk found adrift or stranded on the coast of North America or the Hawaiian Islands, has on examination proved to be Japanese, and no single instance of any Chinese vessel has ever been reported. He explains this by the existence of the "Kuro Siwa," or "Kuro Sibo" (literally black stream), a gulf stream of warm water which sweeps around past Japan toward the north and then curving around passes south along the coast of California, a branch or eddy of which strikes off toward the Hawaiian Islands. This stream corresponds somewhat to the Gulf stream of the Atlantic. It is found that this stream has swept these junks toward America at an average rate of ten miles per day. There also exists an ocean stream of cold water emerging from the Arctic ocean, which sets south close along the Asiatic coast, fully accounting for the absence of disabled Chinese junks in the Pacific, as vessels off these coasts would naturally drift southward.

About the year 1630 the Japanese Government ordered all junks to be built with open sterns, and large square rudders, unfit for ocean navigation, hoping thereby to keep their people isolated within their own islands. When forced out to sea, these rudders are soon washed away, when the vessels naturally fall off into the trough of the sea, and roll their masts out. The number which have thus suffered of which no record exists, must be very large. A noticeable feature in the list given by Mr. Brooks, is that a large number of the disasters on the coast of Japan occurred in the month of January, during which season the northeast monsoons blow the wrecks directly off shore into the Kuro Siwa.

Mr. Brooks, who, as already remarked, has studied the question thoroughly, drew some interesting conclusions from these records, showing that among the coast tribes of our northwest coast, a constant but limited infusion of Japanese blood has occurred, coming entirely from male Japanese seamen; no single record of any female exists. These unfortunate men, often illiterate, and separated from their sources of learning, necessarily lost their own language, but in doing so, doubtless contributed many insulated words to the Indian dialects of this coast; as for example, the Japanese word for quick is *hiako*, and Chenook word for speed is *hyack*. The Chenook word is always an abbreviated word, or shorter word than the Japanese, from which he argued, that the latter was the original and the former derived. The construction of the two languages is, however, different.

In giving the list of wrecks Mr. Brooks mentions a singular circumstance. He says that in 1782 a Japanese junk was wrecked upon the Aleutian islands, from which the survivors were taken in one of the Russian-American company's vessels to the town of Oobotsk, and thence to the inland city of Irkutsk. In 1792 the Governor-General of Siberia ordered the transport "Catherine," then at Oobotsk, to return these men to their native country. The Russian vessel, after wintering in a harbor at the north end of Yesso, proceeded to the port of Hakodate, where the Japanese officials politely but firmly refused to allow their countrymen to land. They were subsequently returned to Siberia again.

In 1833 a Japanese junk was wrecked on the coast of Washington Territory, between Point Grenville and Cape Flattery. Many of her crew had perished, and several dead bodies were found headed up in firkins, in the customary Japanese style, ready for burial. The only survivors, two men and a boy, were rescued from the Indians by the Hudson Bay company's vessel "Lama." Captain McNeal, who took them to England, touching at Honolulu on their way. Thence they proceeded to Canton, where they arrived in 1836, and stopped with Mr. Gutzlaff, who learned their language, and intended accompanying them to Japan. In 1837 they left Macao in the American ship "Morrison," dispatched by Clarence A. King for Yeddo bay, to bear them home. Being fired upon, and prevented from landing, she sailed for Kagosima, where, being equally unsuccessful, she finally returned with the men to Macao. In both instances the Japanese refused to receive their shipwrecked countrymen because they had been in foreign countries and might have learned something detrimental to what were thought to be the best interests of the people. Happily, Japan, is now more enlightened.

Results of Concentration of Ores.

A gentleman well known in mining circles has given us the following statement of the first run of the new concentrating works of Cazin & Fischer, in Denver, Colorado. The method of concentration is known as Cazin's one plunger jig system.

The ore operated on was twelve tons of tellurium, mixed with iron pyrites, from Gold Hill, (Col.), assaying before concentration as follows: Silver, \$14.70 (eleven and three-tenths ounces); gold, \$13.40 (two and one-tenth ounces); total coin value per ton, \$58.10. The assay after concentration gave as follows: Silver, \$117.91 (ninety-one and two-tenths ounces); gold, \$262.50 (twelve and seven-tenths ounces). Total coin value per ton, \$380.40; increase in value by concentration, \$322.31. The tailings assayed three and one hundred and eighty-seven one-thousandths ounces in silver, and one hundred and twenty one-thousandths ounces in gold; value, \$6.27 per ton.

The concentrated material could not be weighed correctly for this lot, being the first fill up of the batteries, jigs, etc. It will be seen by the concentration that about 8 1/4 tons have been concentrated into one. It will also be seen that the concentration of gold is not in the same ratio as that of the silver, the latter increase being 11.3 to 91.2, or 8.3-10 times. If the gold had increased in the same proportion they should have had 16.6 ounces instead of 12.7. It is supposed that the gold will be found in the jigs, sieves, etc., where it would probably remain on account of its great specific gravity.

Looking at this from a metallurgical point of view anyone will at once see the value of concentration. Few smelters would pay anything for ore assaying 11 ounces of silver and two ounces of gold. After concentration the smelter would pay about \$290. The cost of concentrating is about \$3 per ton or \$24 for the eight tons, leaving a balance to the miner of \$266, or \$33 per ton.

The process not only increases the amount of gold and silver but its value also. Ores assaying 50 ounces are worth about 45 cents per ounce when a 400 ounce ore is worth \$1.04 per ounce. Concentration is based on the difference of specific gravity between the metal and the gangue. The greater this difference the more easy the separation. The ore referred to above was operated on had a specific gravity of 2.7 for gangue and 4.5 for the pyrites, while a lead ore would have stood gangue 2.7, galena, 7.75. The samples assayed were taken, not when the concentrator was working at the most favored moment, but from the general average at its normal working condition. It will be remembered that we described Cazin's one plunger jig system a few months ago, and the process is probably familiar to those interested in the concentration of ores. The gentleman who furnished the above facts was staying in Denver at the time the works started and being interested in the subject paid it close attention. He is in no way or shape interested in the works mentioned.

Academy of Sciences.

A regular meeting of the California Academy of Sciences was held on Monday evening last, R. E. C. Stearns in the chair. The donations to the museum were as follows: Nine bone hawks, from an Indian mound twenty-five feet deep and covering two acres of ground, in Visitation valley, South San Francisco; also specimens of bog iron from Queen Charlotte's Island; bog coal from Oak Vale, near Victoria, and Indian stone pistols from Visitation valley—all from James Deane. Species of the ostra, much larger than the ostra or the *O. Tayloriana* of Whitney, from Mrs. John Torrence, at San Marguerite Island, near Paso Robles, San Luis Obispo county. Specimens of petrification, from James Green of Monterey county. Mandarin duck, sent by Professor Davidson from Yokahama. A lot of specimen minerals from E. O. McDevitt, of Brisbane, Australia.

The Secretary read a paper by S. P. Christy, entitled "Notes on a Meteor seen at Berkeley, December 9th, 1874."

The publication Committee recommended the reading of a paper, by E. B. Kirk, "On Changes of Life in North America," which was published in one of the magazines.

Charles Wolcott Brooks read a paper giving a record of the wrecks of Japanese junks, which is referred to in another column.

The death of Sir Charles Lyell was announced to the Academy, and a committee appointed to make fitting allusion to his death.

Mr. J. W. Taylor, formerly of the State Cabinet of Natural History and Geology, will shortly deliver a course of four lectures on Geology and Natural History, in the hall of the Academy. The lectures are independent of the Academy of Sciences, and \$2 will be charged for the course.

The main north drift on the 1500-ft. level of the California mine extending through to the Ophir, is being enlarged to 10 ft. in height by 6 1/2 ft. in width, forming a magnificent air gallery, extending from the Consolidated Virginia to the Ophir. The advantages of such an opening between two mines at such a depth is almost incalculable, and will amply repay the amount expended in its construction.

Among the Foundries and Machine Shops.

The activity in the foundries and machine shops, to which we referred two weeks since continues. A number of new contracts have been made by different firms since our last report.

The Fulton Iron Works

Are engaged in constructing twin propeller engines 14x12 for a lumber schooner now being built to the order of Messrs. A. Duncan & Co. An engine 14x18 and mill machinery complete for a saw mill at Eel river is also being built here for the Springfield Mill Co. This firm in addition to the above are building two large condensers for the New Almaden mines, and are just completing the iron work on an \$80,000 contract for Flood & O'Brien's new iron building on Montgomery corner of Pine street. A contract has also just been awarded the Fulton works for the construction of two engines 20x22 in. bore each, two 74 in. boilers and all the requisite machinery for a new steamer to ply between this city and Humboldt bay.

Pacific Iron Works.

At these works is being constructed a hoisting engine and apparatus for the new shaft of the Consolidated Virginia and California mines. The engine will be 26x72 in. and will be from two to three months in the process of building.

The Golden State Foundry

Messrs. Palmer, Knox & Co., proprietors of the Golden Gate foundry, have just finished a very complete five-stamp battery to be used in a Mexican mine. It will be sent by steamer to Mazatlan, and then packed inland on mules; its weight is but little over 800 pounds.

The firm is also engaged in filling a large contract for 2,600 ft. of 6 in. tubing for air compressor at the Imperial silver mine, Gold Hill, Nevada.

A New Foundry.

Messrs. McCormick & Lewis are actively engaged in the construction of a new foundry on Beale street just below Folsom. It is to be a frame building, at present one story high, and fronting sixty feet on Beale street. The firm contemplates the prosecution of a general foundry business, with, however, principal reference to architectural castings. They expect to have their building completed and their work in operation in about thirty days. The senior member of the firm, Mr. McCormick, has long been a partner in the Vallejo foundry. Mr. Lewis was formerly with the City iron works.

Taxing Mines.

At a most every session of Congress, some enterprising gentleman raises the question of the taxation of mines, or has a scheme for working the mines to pay off the National debt. Considering how very little attention our legislators pay to the mining interests generally, this is somewhat singular. It serves, however, to bring some one into temporary prominence, and give them a chance to air their eloquence. Of course it is only those who are entirely ignorant of mining matters who broach these questions; people who hear about and believe stories about rock assaying \$5,000 per ton and a hundred thousand tons in sight in a single mine. The latest instance of this sort occurred this week at Washington. Mr. Alcorn, of the Committee on Mines and Mining, offered an amendment to tax all corporations working gold and silver, five per cent. on all products over \$100,000 per annum. After considerable discussion the amendment was defeated by a large majority.

We must confess that we do not know anything much of Mr. Alcorn; his name expresses familiarity with agricultural, rather than mineral products; but we are glad to know that his project was defeated. He very probably like many other men, based his ideas of the profits of mining matters on the recent occurrences on the Comstock, imagining that bonanzas of greater or smaller degree, were common occurrences. He thought that since miners were making money out of the ground they were getting more than they ought to reasonably for their labor. It is, in fact, very seldom that miners now-a-days make any great fortunes without hard work for it. Speculator in mining stocks sometimes do this, but the ore not miners, nor do they usually get their riches from the mines. It seems strange that after so many years so little is known by the public generally about mining affairs. The entertain extravagant ideas about profits at cost of work, and no doubt there are plenty of people who really think the miners should pay the National debt, and believe they could do it.

THE Black Hills.—Considerable interest is still manifested in the Black Hills region, and it is probable that before many years that county will be thoroughly preoccupied. Special dispatches from Sioux city say: There is a great excitement in that vicinity at Dakota over reports brought by two returned Black Hills miners, both of whom are well known and reliable men. They represent the gold is plentiful, and that the miners now in those hills have had no trouble with the Indians, and have wintered comfortably. A immense emigration to the hills is expected this spring.

Recent Patents.

Among the Pacific coast patents recently obtained through Dewey & Co's Mining and Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

GANO PLOW.—Howes, Dorr and Webster, Stockton. This invention is claimed to be an improvement on that class of gang plows in which a series of two or more plows are secured to a diagonal timber, which timber forms part of the plow frame. The plows are fastened to a diagonal timber which is strengthened by three parallel beams connected at the other end by a transverse beam. Each plow standard is cast with two arms to which a horizontal flange is secured, the standard being secured to the timber by screws. By this means the plows are easily removable. A draft attachment is provided by employing a bar where opposite ends are bent upwards and fitted in grooves or slides on the inner sides of the beams. These ends are secured at the desired point by a screw moving in a slot. The frame is mounted on castor wheels which can be adjusted up or down so as to raise or lower the plows, and a handle at the end enables the driver to shift the frame. Thus an adjustable draft attachment is provided to raise or lower the point of the plows and regulating the width of the furrow.

IMPROVED RIDDLE FOR SEPARATORS.—Nathan M. Brown, Pescadero, San Mateo county, California. This device relates to improvements in that class of riddles for separators in which one or more middle sections are hinged together and mounted inside the separator frame. The riddle is constructed in two or more sections, each of which is fitted inside of the separator frame. Across this frame are stretched parallel wires, one end of which are fastened to the under side of the frame, while the others are fastened to the upper side. The sections are connected by means of hinges, so that the end of one screen will be below the other; thus connected they are secured inside the frame by link hangers at one end, while the other is supported by a rod. A shaft, provided with arms, to each end of which is attached a crank wheel, supports the rear end of the riddle, by which means a slight inclination is provided, and a blast of wind is secured the whole length of the boxes.

MACHINE FOR TURNING GLOBULAR FORMS.—Andrew J. Kane, San Francisco. This is a machine intended more especially for turning soap balls, but which can also be used for turning globular forms in other substances. In operating, the crude material is placed upon a table directly under a ring which stands vertically and is controlled at pleasure, into which the material is forced. The ring is then turned to a horizontal position and the material is brought in contact with a machine concave in form, which cuts it into a hemispherical form. The ring is then rotated, the machine set in motion and the material shaped upon the table in a globular form.

IMPROVED SUSPENSION BUCKLE.—Edwin J. Fraser, San Francisco. This device is intended as an improvement in buckles now in use for fastening stockings or other suspenders. The buckle is constructed of a narrow strip of plate metal with an end bent so as to form a hook; to the other end is secured a wire ring through which passes an elastic band. Around the body of the plate is secured a flat, sliding hand, and to the lower edge of which is secured a bent lip, which passes over the edge of the hook, and when pushed down beside the fabric so that it can only be released at the pleasure of the wearer.

IMPROVED WATER METER.—Nathaniel W. Knowlton, Nevada City, California. This is a simple but ingenious device for measuring the flow of water through the pipes. It is operated automatically, and by means of two cylinders, one working within the other. A valve is operated which opens and closes subject to the discharge of the water. The smaller cylinder, which raises and lowers, forcing open the valve, strikes an arm in its movements, to which a register is attached, which measures the amount of water flowing through the pipes.

IMPROVED RIFLE SIGHT.—Thomas Dunstone, Santa Cruz, California. This invention relates to an improvement in the front sights for rifles, by means of which one or two different kinds of sights are easily and quickly substituted for the other. These sights are mounted upon a sleeve fitted to turn upon the barrel so that either sight can be brought to the top of the barrel, and there secured by a set screw after being properly adjusted by a gauge or mark. The rotating sleeve is so arranged as to be set back in case a bayonet is used upon the rifle.

DRILL.—George Atkinson, San Francisco. This is an improved churn drill for perforating rocks, and consists in a novel method of operating and rotating the drill and the construction of the frame, so that it and the machinery connected therewith can be easily taken apart. The drill may be worked vertically or at an angle, and by an ingenious arrangement of grinding arm, cam and ratchet, while the drill is allowed to fall by its own weight, or if that is insufficient for the purpose required, provision is made for adding a spring or other weight.

The Santa Cruz "Ruins."

About six miles east of Santa Cruz, and well up into the mountains, there are found some very singular samples of weather-worn sandstone, which from their remarkable resemblance to architectural remains have been designated as "The Santa Cruz Ruins," or the "Ruined City." The illustration given herewith presents a very correct representation of them as they appear when two or three feet of the surface sand is removed from the front. The "ruins" are found on a steep hillside of loose sand, almost entirely destitute of vegetation. The distance from the lowest portion of the pillars which support the arches, as shown, to the top of the highest column on the left is about twelve feet. A person can readily place himself in the opening behind the columns, but farther progress is cut off by the sand which has fallen down and appears to envelop other pillars beyond. The pillars are made up of concentric layers of stone, easily separated, and which are perforated through the center as shown in the two pieces which have fallen down. When first brought to the attention of travelers some twenty-five years ago, there were columns of concentric layers upon the right hand side, similar to those upon the left, but being less firm in position they have been thrown down and mostly carried off by curiosity hunters.

There is no doubt but that other deposits, or

THE "RUINS" NEAR SANTA CRUZ, CAL.

concretions, exist in other positions, further up the hill, but now buried in the loose sand, as detached pieces are met with at an elevation of many feet above the locality shown, which, of course, must have come from still further above.

Many persons have supposed that these are genuine architectural ruins, and an effort was made some five or six years ago to remove the sand from around them so as to lay open to view the base of the supposed pillars; but the sand flowed in about as fast as it could be removed, and the attempt was given up. These singular rocks are, no doubt, the remains of an ancient spring whose waters contained ferruginous or other solutions, which have served to so indurate the sandstone in immediate contact with the water flow, so as to admit of its withstanding the disintegrating action of the elements, which has gradually worn away the surrounding rock, and converted it into a loose sand. By such action a pile of rocks would naturally be left standing just as shown, to be gradually broken down and worn away, as are other rocks of not very firm cohesion. The country rock is chiefly sandstone, interstratified here and there with slates.

A small stream of water flows along, some three hundred feet in front and sixty or seventy feet below the spot shown; while a much larger one skirts the opposite side of the hill, into which the smaller one empties, a short distance to the west of the base of the hill. The action of these two streams, aided by the winter rains, is gradually washing away the sand hill, and will in time, no doubt, completely unearth all that remains of these singular concretions.

Several very inaccurate views of these "ruins" have been given, one of which appeared in Frank Leslie's paper of June, 1858, which represent a stream of water as issuing out from beneath the arches shown in our illustration, while as a matter of fact the stream is several hundred feet distant, and nearly a hundred feet below; otherwise that illustration was quite correct. The illustration given in the California Geological Reports is quite as far from a genuine representation as it is from the one given herewith. In fact, we believe this is the only correct representation of this singular locality which has ever been presented to the public. Those who have visited it will at once recognize its correctness. The "ruins" are located upon the ranch of Mr. D. M. Locke, the husband.

Origin of California Land Shells.

The following paper was read by Dr. J. G. Cooper, formerly of the State Geological Survey, at a recent meeting of the California Academy of Sciences:

In previous articles I have given some observations on the Distribution and Variations of the California Banded Land Shells, which naturally lead to the consideration of their probable origin or past history.

In the "Bulletin of the Museum of Comparative Zoology, Cambridge, Massachusetts, June 1873," p. 202, Mr. W. G. Binney writes: "The West alone is left to us from whence to trace the pulmonate Fauna of the Pacific region, and there the secret of its origin lies buried under the Pacific ocean."

Mr. Binney probably alluded to the supposed existence of an oceanic continent in the South Pacific, embracing the mountain summits now forming the archipelago of Oceania, which became submerged, as Professor Dana suggests, during the latter tertiary period, while most of California was emerging from the ocean.

When California Rose from the Sea.

But even if this were proved to have happened; the great distance of the nearest islands (the Hawaiian) from us, and the great depth of the ocean between, as well as north of them, besides the total dissimilarity of their living land shells from ours, forbids any supposition of a former land connection by which such animals could travel directly from one country to

present North Pole, the subsequent gradual cooling of those regions, which is supposed to have driven the living species of redwoods southward to California and Japan, as well as other trees into Europe, would, if a slow change of climate, also drive southward the land mollusks, "at a snail's pace" into the same regions, where we now find their descendants occupying countries which are about equidistant in longitude around the Northern Hemisphere, in latitude 40 deg. and 50 deg.

We have strong confirmation of this theory in the well known distribution of circum-polar species of land shells southward, on both continents along meridians of similar temperatures and along mountain ranges; (especially those running southward as in America), and which are supposed to have thus migrated south during the "Glacial epoch."

Tertiary Remains of Animals.

Besides these two groups, the "circum-polar" and the "representative" species, we also have on the west slope a very few of the Eastern American type. I do not, however, consider these as evidence of migration westward, but would explain their occurrence as proving a former existence of ancestors common to both in the middle regions of Oregon and Nebraska, where are found so many tertiary remains of animals that once inhabited both regions before the Rocky mountains became a barrier to migration or caused different climates. The few fossil land shells yet found in California are not sufficiently abundant or ancient to furnish data for their geological history. The freshwater forms, however, indicate a very different and more tropical group in the Pliocene and Miocene strata, which I hope at some future time to describe and illustrate. The occurrence of pupa and cornulus in the carboniferous strata of Nova Scotia shows that land shells existed long before the Eocene period. The great northern glacial period, and local glaciers further south, have so generally destroyed the softer tertiary deposits, that it must be long before the traces of a migration can be traced from Greenland southward, but as tertiary land plants are found there fossil, some similar deposits must have escaped elsewhere. There can be no doubt that the local migration has been westward along this coast, from the facts before stated as to the occurrence of species in the coast ranges and islands, which are unquestionably Miocene and Pliocene in age, while their allies in the Sierra Nevada may have existed there since the Eocene, but at a greater elevation than they are now found. As they move westward, we also find the few older forms developing into many "specialized" varieties. Species much like the living ones of California may be expected to occur in the Pliocene of British Columbia. Going south of California we find further confirmation of the theory of southern migration, in Mexico, where species closely resembling the *Pomatia* of Europe occur on the higher mountains, which, unless special creations, could only have reached the two regions by a process like that which I have described. The genera *Bulinus*, *Glaudiata* and *Clavusilia* may also have traversed a similar route, though their absence in

The Tertiary Strata of the Eastern States

Seems to be evidence to the contrary. They may, however, be found in the territory of the "Great Basin," which is known to contain fossils of some other genera now found only south of the United States (*Berendtia* and *Holospira*). Indications, however, are known which point to a connection of tropical regions by land in tertiary times, independent of a polar route. The supposed "Atlantis" connecting South America with Africa would also have connected it eastwardly with Asia and Oceania.

The Humble and Despised Snail

Thus become among the most important evidences of geological changes and conditions of the land, climate, etc., in the past history of the globe. Being terrestrial and easily preserved, when of moderate thickness, they furnish evidence not supplied by any other class of fossils, while their persistency of types is shown by the close resemblance of the carboniferous species to modern tropical forms. One species at least is found only fossil in England (in Pliocene or later strata) which still lives in the Eastern States, like the trees found under similar conditions, and careful examination of fossil forms on both continents will no doubt show other curious coincidences. It may be mentioned, also, that genera, of abundant occurrence in the Eastern States, have as few representatives in Europe and Asia as they have on this coast. Every fact like this tends to prove that their former migrations have not been to the east or west, but from a common northern center toward the south.

PARTIES just from Galice Creek, Oregon, says the Jacksonville Times, express the opinion that the ledge lately discovered by D. Courtney is likely to prove richer than the other quartz mines found. It is a few miles distant from the scene of the other discoveries and about 100 feet in width.

A POCKET of rich decomposed quartz has lately been found by some Portuguese over on Rush creek, Nevada county. From the same ledge a colored man took out \$12,000 several years ago. So it goes; abandoned but not played out.

MINING operations in Baker county will be conducted on a larger scale this year than ever before, and the prospects are that the results will be very gratifying to miners and advantageous to that part of Oregon.

Where the Redwoods Came From.

It is easy then to see, that having their central position (if not origin) in points so near the

Ayer's Hair Vigor

RESTORING GRAY HAIR TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sickness, care, disappointment, and hereditary predisposition, all turn the hair gray, and either of them incline it to shed prematurely.

AYER'S HAIR VIGOR, by long and extensive use, has proven that it stops the falling of the hair immediately, often renews the growth, and always surely restores its color, when faded or gray. It stimulates the nutritive organs to healthy activity, and preserves both the hair and its beauty. Thus brassy, weak or sickly hair becomes glossy, pliable and strengthened; lost hair regrows with lively expression; falling hair is checked and established; thin hair thickens; and faded or gray hair resume their original color. Its operation is sure and harmless. It cures dandruff, heals all humors, and keeps the scalp cool, clean and soft—under which conditions, diseases of the scalp are impossible.

As a dressing for ladies' hair, the Vigor is praised for its grateful and agreeable perfume, and valued for the soft luster and richness of tone it imparts.

Quartz Mill for Sale

At Mineral Hill, Elko County, Nevada, four miles from Mineral Hill Station, on the Palisade and Eureka Railroad, and 35 miles from the Central Pacific Railroad.

The Mineral Hill Silver Mines Company (Limited) offer for sale their new 20-stamp mill (dry crushing) built by H. J. Booth & Co. of San Francisco.

The mill is complete in every respect, with engine, Boilers, Stetefeldt Furnace and all modern appliances, and is as good as new, having only run two months upon ore.

The whole is offered very cheap for cash. For further information apply to

H. H. OAKES, Superintendent.

Mineral Hill, Nevada.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleaning Woolen Fabrics, Cutlery, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Bathing. It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a washbowl of water. For bathing, use one table-spoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterwards. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing, and the preparation of artificial manures. AMMONIACAL PREPARATION for the prevention and removal of boiler scale. CRUDE AMMONIA for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they

have no equal. No effort has been, or will be spared

to have them constructed in the most perfect manner

and of the great number now in operation, not one has

ever required repairs. The constant and increasing de-

mand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly

into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces

the pulp to the center, where it is drawn down through

the aperture and between the grinding surfaces.—

Thence it is thrown to the periphery into the quicksilver.

The curved plates again draw it to the center, where it

passes down, and to the circumference as before. Thus

it is constantly passing a regular flow between the grind-

ing surfaces and into the quicksilver, until the ore is

reduced to an impalpable powder, and the metal amal-

gamated.

Settlers made on the same principle excel all others.

They bring the pulp so constantly and perfectly in con-

tact with quicksilver, that the particles are rapidly and

completely absorbed.

Mill-men are invited to examine these pans and settlers

for themselves, at the office, 229 Fremont Street,

San Francisco.

OVER \$3,500 PER MONTH SAVED
 BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1875.
 JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:
 1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
 2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
 3d. They are good amalgamators, light (leathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
 4th. They require but little power and attention to run them, and with ordinary care will last for years.
 I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Orass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co., St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,
 Yours respectfully,
 JAS. H. CROSSMAN, M. E.
 409 California street, or Cosmopolitan Hotel.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.
 MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them, and the saving to the company has been over \$3,500 per month more than with the blankets and buddles formerly in use.
 O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.
 J. HENDY, Esq.—Dear Sir:—Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.
 As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection.
 E. R. BURKE, Superintendent.

For description send for Circular.

JOSHUA HENDY, San Francisco.

3v28-1m-1f

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
 Price Reduced to 16 Cents Per Pound.
 SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

1v29-3m

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air, stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ore, heating the water for amalgamation and the rollers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to Mining and Scientific Press, No. 18, October 31, 1874. For particulars address

D. B. MILLER & CO.,

No. 12 West Eighth Street, Cincinnati, Ohio
 Circulars, etc., will be furnished, if required.

Stockholders and Mines.

In the Nevada Legislature they have been having quite a little breeze over Shepherd's bill allowing a stockholder owning five shares of stock of the par value of \$500 in a mine to have the right to inspect the same. It was considered that the bill gave poor men the same rights as rich ones, and it provoked considerable discussion. An amendment was offered that any person representing \$20,000 in stock should be allowed to inspect the mine, but this was lost.

Stevenson opposed the bill, because although the principle is good, if it became a law it would prove inoperative. If a man owning this stock went down the mine he would know nothing about it, the mine being all in darkness and the stockholders not being acquainted with drifts. If the bill was to become a law it should have been drawn so as to include the providing of guides, and should be prepared by some one knowing the "tricks that are dark and the ways that are vain" of mining superintendents.

Clapp said that there were other places in the State beside the Comstock where mining was carried on, and there were several mining camps where such a law would prove effectual and be a good one.

The bill was finally defeated by a vote of ten to fourteen.

It seems but simple justice that a stockholder owning five shares should have the same rights in the mine as those owning five hundred, as far as examining it is concerned. But, after all, it would be sure to work serious inconvenience in large mines were every stockholder allowed to go and come in the mine when he pleased. It would really be detrimental to the interests of those stockholders who have not time to examine the mine. Almost the entire machinery would be used in transporting visitors, as the stock could be loaned to any person who desired to visit the mine. It would inconvenience the workmen and cause considerable expense and trouble.

On the other hand why a small stockholder should not visit the mine as often as a large one if he chose, is not clear. It might do something to prevent "corners" in stock jobbing operations, if all holders of stock could visit mines. But after all a law such as is proposed would be inoperative and of no avail with the majority of stockholders. Most of the stock in Comstock mines is held in this city, and few real owners here would ever have a chance to go to the mines. Moreover, very few would want to as they care little really about the mines and simply speculate in the stock. If a law was passed such as above referred to, the people here might give a few shares to some individual in Virginia, so that he could report, and that is all the good it would do to citizens here. Stockholders, in Virginia, however, might have been benefited to some extent.

Another Arctic Expedition.

A Washington dispatch says it is proposed to provide a small sum in the Sundry Civil Appropriation bill for an Arctic expedition. The Secretary of the Navy favors it, also a number of Senators and members. The Navy Department will be authorized by the bill to provide and fit a proper ship and man it with officers and men already under pay and awaiting sea duty. The extra expense will not be more than \$50,000, but it is proposed to take action by the Government, contingent on private subscriptions to the amount of \$25,000. The President of the Geographical Society says it will heartily co-operate in any expedition, whether undertaken by the Government or private enterprise. The very bad luck of the last Government expedition to the Arctic, when poor Hall met his death, will probably, prevent many people from looking with favor on the idea of another expedition. On the other hand, the success of the Austrian party last year is an incentive to the Government to maintain an honorable position in the history of Arctic research. It is not in keeping with the American character to back out because obstacles are great, but to endeavor to overcome them. An English expedition reassured by the results accomplished by the Austrians, has been formed; and after the United States has spent so much money, and lost so many valuable lives, the Government does not like to retire from the field and acknowledge itself defeated, more especially, since it now has Arctic possessions—Alaska. There is one thing, however, that we think should be inquired into. That is, the feasibility of attempting to reach the much talked of "open polar sea" by trying on this side of the continent. The obstacles on the other side are great and difficult to be overcome. We all know what and where they are. A beaten path is laid out and the only difference in many of the expeditions was as to where they were frozen in, and how far north they got. No attempt has been made on this

side. The young Frenchman Pavy, who came here a few years ago to start up on this side, never made the attempt; simply, however, from lack of means. At the time he was in this city, the writer heard him give, before the Academy of Sciences, his reasons for believing that an expedition would be more successful, which made an attempt to reach the open polar sea by going up through Behring's straits. His argument was good and the plan was looked upon as very reasonable by those familiar with the subject. It seems to us, accordingly but proper, that the Government should take into consideration the fact that no attempts have ever been made on this side of the continent to solve the questions, which Arctic expeditions are expected to solve. The majority of people do not see the benefit of such expeditions at all, but scientific men and other searohers after knowledge do not like to rest on hard earned but insufficient results, without solving the whole problem. Accordingly expeditions will continue to be sent in all probability until all questions concerning the North Pole are at rest. We have perhaps learned all we ever will of Sir John Franklin and his men. But the "North-west passage," the open polar sea and what lies beyond must be studied up. Perhaps when governments get tired of trying to find a passage through the icy barriers of the North on the other side, some one of them will send an expedition to the North Pacific and attempt to learn the mysteries of the Arctic by taking a new road. There is no question but that the idea should be investigated by those in authority, and some steps taken to see what could be accomplished.

QUICKSILVER IN S. F., by the flask, per lb, \$1.32 1/2.

AN AWFUL RESPONSIBILITY.—Everybody has something to say about consumption. We all deplore its terrible ravages, but only a few of us have common sense enough to take the proper means of preventing it. It is a fact as easy of proof as that two and two are four, that *Hale's Honey of Horehound and Tar*, taken as a remedy for cough, cold, difficult breathing, hoarseness or any other of the symptoms, which, as it were, pave the way for that terrible destroyer, will effect a radical and rapid cure of the ailment, and avert all danger. Whoever, knowing this, neglects to resort to the true specific under such circumstances, assumes a fearful responsibility.

Pike's Tooth-Ache Drops—Cure in one minute.

STEEL SHOES AND DIES.—There is an exhibition at the office of the Cast Steel Shoe and Die Company, 330 Pine street, a shoe and die that were used constantly at the Morgan mill, Empire city, for over four months. The shoe is worn down to within less than an inch of the stem, but still presents a remarkably even surface. The die lasted nearly six months, and there is nearly two inches of it left. Those interested in such matters should call and examine these samples.—Exchange.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SOLENTIFIO PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch. Dated Washington, D. C., March 2, 1875.

FOR WEEK ENDING FEB. 16, 1875.*

DREYER FOR REFINED SUGAR.—August F. W. Partz, Oakland, Cal.
CAR SPRING.—Andrew Jackson Culbertson, San Andreas, Cal.
SEWING MACHINE FOR STITCHING SACKS, San Francisco, Cal.
FLUX FOR TREATING ORES.—P. N. Mackay.
EYELETING MACHINE.—John Coombe, San Jose, Cal.
SMOKE CONSUMING FURNACE.—W. L. Powelson, S. F. Cal.
HOOF TRIMMER.—Andrew Shitran and Wm. J. Givens, Pacheco, Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with effect and security and in the shortest time possible.

Banking.

DIVIDEND NOTICE.

French Mutual Provident Savings and Loan Society.—Thirtieth Semi-Annual Dividend.—A dividend of eight 1/10 per cent. per annum (net 8 1/10 per cent.) has, in conformity with the report of the Committee of Verification appointed by the members of the Society, been declared at the annual meeting, held on the 15th instant. This dividend will be payable on and after the 18th instant, at the office of the Society, 411 Bush street. GUSTAVE MAHE, Director French Savings Bank.

DIVIDEND NOTICE.

Masonic Savings and Loan Bank, No. 6 Post street, Masonic Temple, San Francisco. G. MAHE, Director.

To Patent Attorneys, Contractors and Inventors.

WASHINGTON, D. C. January 1st, 1875.

I have carefully prepared a complete digest of U. S. patented Paving and Roofing Compositions, up to January 1st, 1875, in which is given the name of patentee, number and date of patent, ingredients, and, (when given in the specification) the proportions of ingredients. Also, all of English Patented Paving Compositions up to January 1st, 1874, amounting in all to over six hundred patents, a complete state of the art to date. It is my intention to publish this work at an early day in book form, and should you wish to subscribe should address

TO COPPER SMELTERS, BLUE-STONE
and Sulphuric Acid Manufacturers.

For sale or to lease, the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations realized \$30,000 for Bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction, \$1. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. of pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Louis Chalmers, Silver Mountain, Alpine county, Cal.

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.

[Covered by Letters Patent of July 2d, 1872, and recent applications.]

Containing a sizing apparatus, (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having five sieves, each row concentrating according to specific gravity the special size automatically fed into it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d-class ores into 1st-class ores of perfect cleanness. It thoroughly separates native gold or copper from quartz or any other lode matter—galena and silver sulphurets from pyrites, baryta and quartz; and pyrites from quartz. Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

F. CAZIN, M. & C. E.

Supt. Denver Concentration and Smelting Co
At Denver, Colorado, Lock-Box 2226, or corner of
Blake and 32d streets. ags-16p

pany.—Principal place of business, City and County of
San Francisco, State of California. Location of works,
Cherry Creek Mining District, White Pine County, Ne-
vada.

Notice is hereby given that at a meeting of the Board
of Directors, held on the 2d day of January, 1875, an assess-
ment of twenty cents per share was levied upon the
capital stock of the corporation, payable immediately in
United States gold coin, to the Secretary, at the office
of the Company, Room 14, 302 Montgomery street, San
Francisco.

Any stock upon which this assessment shall remain un-
paid on the 5th day of February, 1875, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Monday the 1st day
of March, 1875, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.
J. T. MILLIKEN, Secretary.
Office—Room 14, No. 302 Montgomery street, S. F.

POSTPONEMENT.—The time when the above assess-
ment will become delinquent is postponed to the eighth
(8th) day of March, and the sale of stock for delin-
quency is postponed to Wednesday, the thirty-first
(31st) day of March, 1875, at the usual hour and place
above mentioned. By order of the Directors.
J. T. MILLIKEN, Secretary.
San Francisco, Feb. 2, 1875.

Kearsarge Consolidated Quicksilver Min-
ing Company.

Notice is hereby given that at a meeting of the Board
of Directors, held on the 29th day of December, 1874,
an assessment, No. 1, of 30 cents per share was levied
upon the capital stock of the corporation, payable im-
mediately in United States gold and silver coin to the
Secretary, No. 408 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the eighth of February, 1875, will be delin-
quent, and advertised for sale at public auction, and
unless payment be made before, will be sold on Wed-
nesday, the 22d day of February, 1875, to pay the delin-
quent assessment, together with costs of advertising
and expenses of sale.

JAMES McHAFFEE, Secretary.
Office Rooms, 10 & 11—No. 408 California street, San
Francisco, Cal.

Kincaid Flat Mining Company—Loca-
tion of principal place of business, San Francisco, Cal.

And in accordance with law, and an order of the
Board of Directors, made on the 8th day of January,
1875, so many shares of each parcel of such stock as
may be necessary, will be sold at the office of the com-
pany, 18 and 15 Fremont street, San Francisco, Califor-
nia, on the 18th day of March, 1875, at 12 o'clock, M., of
such day, to pay delinquent assessments thereon, to-
gether with costs of advertising and expenses of the
sale.

L. L. ALEXANDER, Secretary.
Office—13 and 15 Fremont street, San Francisco, Cal.

Silver Sprout Mining Company—Princi-
pal place of business, San Francisco, State of Califor-
nia. Location of works, Kearsarge Mining District,
Inyo County, California.

Notice is hereby given, that at a meeting of the Board
of Directors, held on the 17th day of February, 1875, an
assessment of five cents per share was levied upon the
capital stock of the corporation, payable immediately in
United States gold and silver coin, to the Secretary, at
the office of the Company, in San Francisco.
Any stock upon which this assessment shall remain un-
paid on the 17th day of April, 1875, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Thursday, the 15th day
of June, 1875, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

T. B. WINGARD, Secretary.
Office—Room 13, No. 318 California street, San Francisco.

Tuolumne Hydraulic Mining Company.
Principal place of business, city and county of San Fran-
cisco, State of California. Location of works, Tuolumne
county, State of California.

Notice is hereby given, that at a meeting of the Board
of Directors, held on the 23d day of February, 1875, an assess-
ment of twenty (20) cents per share was levied upon the
capital stock of the corporation, payable immediately in
United States gold coin, to the Secretary, at the office
of the company, room 14, 302 Montgomery street, San Fran-
cisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the 23rd day of March, 1875, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Saturday, the seventh
(7th) day of April, 1875, to pay the delinquent assessment,
together with costs of advertising and expenses of sale.
J. T. WINGARD, Secretary.
Office, Room 14, 302 Montgomery street, San Francisco,
California.

SELF-LUBRICATING.

FOR

Locomotive

Marine and

Stationary

ENGINES.

FOR

Steam Pumps

AND

Hot or Cold

Water Pumps

OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Hemp to be found in the market. It is manufactured in a shape the most convenient to use and holds, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box tight. ENGINEERS, TRY IT. For sale in any quantity by TREADWELL & CO., San Francisco.

VOLUME XXX
Number 11.

Hydraulic Mining in California. No. 10.

Sluice Boxes.

This pavement should be built in separate compartments of six or eight feet length, confined by pieces of strong plank or scantling fixed permanently across the bottom of the flume, to protect the pavement against a wholesale destruction in case the current of the stream should dislodge some stones in one or the other of the compartments. For 12 feet of double sluice, equal to 144 square feet, about nine tons of stone are required for paving. (See Fig. 1).

The sluice boxes should be lined above the stone pavement with two inch planks or two inch blocks, for a height of 10 or 12 inches, to protect the real sluice against the wear and tear of the swift gravel stream. (See Fig. 2).

The single sluice in the tunnel must be paved with square pine blocks, about 10 inches deep. These blocks are laid across the flume, close together, and a piece of plank one and a half by six inches is nailed to the lower part of the blocks with headless nails. These headless nails are not driven home, but project about an inch on the face side. A new tier of blocks is inserted and driven on the projecting nails till the blocks touch the intervening board or plank, and are therefore within one and a half inches of the first tier. Another piece of plank is put in position and the same process continued. The lining of the sluices is placed so low down that it touches the tops of the planks in the bottom, and keeps them in position. These spaces of one and a half inches in width separate the different layer of blocks and form the real riffles to catch gold or amalgam. The lining in those sluices which have rock pavements is, in many instances, placed so low that the rock pavement covers about two inches of it. This is done to prevent the wear of the rock pavement leaving a part of the sides of the flume, or sluice, unprotected. This, however, may be an unnecessary precaution, as the lining of the flume wears out much faster than the rocks, and can, when it has to be renewed, always be placed close to the rock pavement.

The expense of constructing a double sluice of the above dimensions depends both on the cost of material used and the difficulty of establishing the proper grade. In localities where lumber can be furnished for \$20 per M, and where the grading can be done without blasting, double sluices have been laid and paved in the most substantial way for \$2 per foot. A single sluice, six feet in width and three feet high, can be constructed, under similar favorable circumstances, for about \$1.25 per foot.

Under Currents.

These are large flat boxes, or platforms, placed beside and a little below the main sluice boxes. Their size and shape depend, to some extent, on the facilities which the place offers where they shall be constructed. Triangles, irregular oblongs, and parallelograms, containing a surface of from 500 to 1,000 square feet, are the forms often resorted to. The under current is destined to receive from the main sluice boxes a certain portion of the finer gravel-wash, black sand, quicksilver, and amalgam, and to afford to the particles of gold and amalgam a better chance to settle permanently in the riffles, which are evenly distributed over the whole surface of the platform. For this purpose an opening is cut across the bottom of the main sluice boxes from 15 to 18 inches in width. In this opening are inserted steel bars, one inch square and one inch apart, generally fixed in a cast iron frame. The small particles of gravel, sand, gold, etc., which pass through this grating are caught in a box placed below the sluice boxes, on a pitch of about one inch per foot, whence they are carried upon the large platform provided with riffles.

This platform is placed on a grade of from 10 to 12 inches per 12 feet, and is provided with an opening at the lower end to return the bulk of the material received to the main sluice boxes below.

To distribute evenly the water and gravel received from the main sluices a number of check boards are placed at the upper part of the platform, in a direct line with the box under the grating of the main sluice, which receives the discharged matter. As the water,

etc., rushes out of this box part of it strikes against the nearest check board and is turned down the platform; the remainder, rushing on, is diminished by each succeeding check board, and an even distribution over the whole platform is gained. At the lower end of the platform the discharge of the water, etc., into the main sluice below may be arrested by the insertion of a small box, on a grade, into which the material drops from the riffles. These riffles can be made either of two by three inch scantlings, laid down lengthways and two inches a part, or of common blocks or stone pavement.

The under current and main sluice boxes discharge their contents into a deep and strongly

Fig. 1. Sluice-boxes; grade 6 in. per 12 ft.; sides 36 in. high; 1, 2, 3, compartments.

built box, provided with a heavy stone pavement. From the upper part of this box a continuation of the main flume leads the gravel-stream to other under currents, drops, etc., and to a final discharge. The lower part of this box must be four or five feet deeper than

Wilcox's Improved Steam Pump.

William C. Wilcox, of this city, recently obtained through the MINING AND SCIENTIFIC PRESS Patent Agency, a patent for an improvement in steam pumps. The improvement consists in certain novel arrangements of valves and the means of operating them, by which greater effectiveness of action is obtained for the engine, while the pump is so constructed that it will throw water in unlimited quantities without choking thus allowing the engines to be run at a high rate of speed.

W. C. WILCOX'S PATENT STEAM PUMP.

the point from which the main sluices are continued—ad and be found of great service in catching amalgam, etc.

The gratings in the main sluices deprive the latter of a quantity of water. To counteract

Fig. 2. Block Pavement for Sluices.

this loss the main sluices are narrowed about six inches to condense the current of water till both streams, that of the under current and that of the main sluice boxes, re-unite as described above.

These under currents are of the greatest service in catching rusty gold, which cannot be touched by quicksilver, and which, lessened in specific gravity by foreign matter clinging to it, is very liable to be carried entirely through a long line of sluices to the final discharge.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

apart and put together again. Still another desirable quality is the wonderful velocity at which they can be run, the inventor claiming that they can be run at least one-third faster than any other pump in use, and at the same time can be run as slowly as may be desired.

From the construction of this pump it must of necessity be durable. Their work is almost noiseless and the stream thrown very steady. From the simplicity of construction they are very cheaply built. This is a recent California invention, and has attracted considerable attention from machinists and others. The pump is adapted for feeding boilers with high or low pressure engines, for tank purposes, for railroad and residences, irrigating purposes, and for water works of any magnitude. They are furnished under a strict guarantee as to the work they will perform. We have seen this pump at work, and are satisfied that it will be well liked wherever introduced.

The pumps are being made in Jonathan Kittredge's building, No. 18 and 20 Fremont street, opposite Spaulding's saw factory, where they can be examined by those interested.

The construction of the Richmond refining works has opened a new branch of industry, that of bone gathering. Bone-dust is required in large quantities for refining, and it will take all that can be found in Nevada to meet the demand.

California Woods — Useful and Ornamental.

Messrs. Editors:—A correspondent's inquiry of J. O. C., as to where specimens of California woods can be obtained for the purpose of manufacturing presents for Eastern friends, has been accidentally overlooked.

In reply I would say that A. Sinning of Coulterville, lately in the Yosemite Valley, would be the best person to apply to for strips of rare woods, suitable for paper folders. I have obtained strips and very beautiful veneers from Strable & Co., billiard table manufacturers in San Francisco, which I have had finished at cabinet makers, or in ordinary carpenter shops. Portfolio covers, made of Oregon cedar, and ornamented with photographs of the same tree are cheap and pretty. Redwood is rather dark, and is improved by gluing on a light border of some other wood which makes the frame to the picture. For paper folders, the small stereographic photographs to be had at Houseworth's or Watkins', of the Big Trees, yellow pines, sugar pine and other Sierra trees are large enough. They should be put on with the decalcomanie process. Below is a list of dark and light colored woods suited to ornamental works. Two years ago, my son collected thirty species of woods in and around the Yosemite, some of which exceed in beauty any foreign woods I know. The two-leaved pine is exquisitely marked, and watered like the richest brown moire antique. Manzanita has the lines of old wine. "Granite" is curiously waved with brown and amber. When we get our shops for the education of female artisans many beautiful pieces of cabinet work will demonstrate the aptitude of our native woods for the finest uses of art. But here is the list: Light woods—Willow, Maple, Frangula, (very fine spotted); Torreya, (California nutmeg); Ceanothus, Silver Fir, Box, Oregon Cedar, Yellow Pine, Two-leaf Pine, Madrone, Buckeye. Dark woods—Manzanita, Granite, Big Tree, Black Oak, Mountain Mahogany, Bear Berry, Live Oak, Red Oak, Redwood (root), Alder. This list is by no means complete, our coniferous trees alone furnish more than thirty different kinds. These suggestions will do for a beginning. JEANNE C. CARR.

GROWTH OF MAN.—Observations regarding the rate of the growth of man have determined the following interesting facts: The most rapid growth takes place immediately after birth, the growth of an infant during the first year of its existence being about eight inches. The ratio of increase gradually decreases until the age of eight years, at which time the size attained is half that which it is to become when full grown. After five years the succeeding increase is very regular till the sixteenth year, being at the rate for the average man of two inches a year. Beyond sixteen the growth is feeble, being for the following two years about two sixteenths of an inch a year; while from eighteen to twenty the increase in height is seldom over one inch. At the age of twenty-five the growth ceases, save in a few exceptional cases. It has furthermore been observed that, in the same race, the mean size is a little larger in cities than in the country, a fact that will be received with doubt by many who have come to regard the rustic as the true model man.

On the 26th ultimo the Oceanic company in San Luis Obispo shipped the last of 300 flasks of quicksilver, being the product of eight weeks' run. The last 100 flasks came out in the last 10 days, being at the rate of 10 flasks per day, or about 800 pounds, worth at the mine \$1,200.

The narrow-gauge company of Salinas and Monterey has just received another locomotive from Philadelphia, at a cost of \$8,000.

The avalanche in Big Cottonwood, Utah, which buried five men and seven teams, was a mile and a half long and half a mile wide.

DURING the last fifteen years Vancouver Island has sent to San Francisco 259,341 tons of coal.

CORRESPONDENCE.

Reveille Mining District.

[From our Regular Correspondent.]

EDITORS PRESS:—Some of the mining camps of Nevada appear to be as little exempt from the laws of change as are nations and individuals. They have their intervals of prosperity and adversity, their periods of brilliant promise and unclouded hope, bright and radiant as the noonday sun, as well as their moments of midnight gloom, neglected and uncared for by the denizens of more fortunate sections. These experiences are, of course, inseparably connected, in a greater or less degree, with the history of silver mining on this coast. They not unfrequently result, however, from the carelessness and lack of energy and vigorous enterprise displayed by early discoverers, who oftentimes leave fortunes behind them in the ground which others by and by successfully develop. Time, labor and money are the three greatest essentials to success in connection with mining, and without the judicious association and co-operation of the two latter there cannot much permanent prosperity result from it. Nature has lavished her treasures with no sparing hand on the bleak and rugged hills and mountains of Nevada, and though she has in some instances largely exposed her mineral wealth, in huge deposits above their rock ribbed sides, with a view to tempt the cupidity and enterprise of the votaries of fortune, she has more generally hoarded it with jealous care, away down in the primitive vaults and channels artistically fashioned by her own imperishable hand. She has, however, left behind her ample evidences of her good will to man, by seeming the otherwise barren rocks and soil with the external indications which, if followed, eventually leads to success. Her vast resources, however, are reached by the same means that subjects the lightning's flash to man's imperious will. The twin sisters, Art and Science, furnish the keys that unlock the chambers where silently repose the mighty secrets and illimitable resources that are stored in the treasury of Nature for the uses and purposes of the material world. Art creates and fashions the plastic material according to prescribed rules while the unerring principles of science direct and instruct in all that relates to its application.

But to resume. The district whose name forms the caption to this letter furnishes an apt illustration of the truth of its opening sentence. It has had its days of gloom, neglect and idleness; it now promises to have the reverse of these; i. e., if I am permitted to draw my deductions from surrounding objects and circumstances, this

Once Famous

District is again beginning to attract the attention of the mining world. Already the fame of its recent discoveries has resounded throughout the State, gladdening the hearts of many who for long years have clung tenaciously to its fortunes, fervently believing that some day they would be amply rewarded for their toil and patience. The citizens of the "Queen City of the Pacific," too, it would appear, have caught the inspiring sound, to judge by the evidences before me. These glad reports reached myself at Tybo, and in order to test their truth I came here on the 16th instant to see and be convinced if possible; if not, to return a sadder and wiser man. I did not return as yet, however, for I have not only seen and examined, but have also become thoroughly convinced of the correctness of the first intimations which I received of its mineral developments; and since one attested fact is worth a score of grape vine reports, I submit the following for the consideration of the numerous readers of the Press:

Reveille District

Was organized some time in 1866, and flourished apace for a considerable time, or until the imbecility, inexperience and mismanagement of the Manager of a New York company, which was formed for the purpose of reducing its ores, had well nigh plunged it forever into the abyss of total oblivion. The structures (wood and brick) that composed the former town, are still standing, and in a tolerable state of preservation, but are no longer tenanted, for they have lately fallen to the lot of the stalwart new comers who, like myself, have been attracted hither. The mines are located on the elevated chain of hills that stretch parallel to and midway between the Diamond range on the west (sometimes called the Hot Creek range), and the White Pine range on the east, which courses north and south. Enclosed between these extended barriers is a broad and fertile valley, suitable for either cultivation or pasture, to the latter of which it is at present devoted, there being

thousands of head of fat, sleek stock roaming at will over its broad expanse. Here too are found a few comfortable grain, hay, and vegetable ranches, whose products find ready market in the neighboring settlements of Reveille, Tybo, Hot-Creek, etc. It lies about 135 miles due south of Eureka, and 35 miles south of Tybo, and is on the direct line of the proposed narrow-gauge to the Colorado river. There is an abundant supply of wood and water for all practical purposes both at the town and mill-site, of which more anon. The geological formation is of limestone, and it is extending in huge projections above the general surface are great veins or belts of quartzite, rich in chloride and sulphurets of silver. Many of these masses of quartz are upward of 100 feet in thickness, and extend longitudinally many times that distance. Great dikes of porphyry are also found coursing in parallel lines to the quartzite and lime. The silver-bearing veins occur most frequently between the two former, the quartzite in most instances forming the foot wall, while the porphyry forms the hanging wall to nearly all the veins examined. The mineral characteristics are quite different from those exhibited at Tybo or elsewhere, though the dip of the lodes is usually to the east and northeast, the same as at Tybo, while the angle of inclination is considerably greater. A large amount of work appears to have been done near the surface, but no great depth has been attained, and herein lies the true cause of the failure of Reveille in early days to meet the expectations formed of it.

The Gila

Mine owned by the company of the same name of which I will speak by and by, makes a fine showing of the sulphuret and chloride ores which give assay values ranging from \$80 to \$1,400 per ton and in a few instances even higher results have been obtained. Three samples recently taken at random from the inclined winze now being sunk on the vein, which shows a thickness of four feet between walls, yielded as follows: No. 1, a fine chloride ore, \$883 35; No. 2, \$405 15; No. 3, \$150 20; an average of \$479 23, in silver; no assay being made for gold, though I am certain that it is present in greater or less amounts. Quantities of this ore worked at the Tybo furnace, gave returns of \$850 per ton. The percentage of lead is very light, being hardly 3 per cent., thus giving promise of being easily and profitably melted. This mine is located on the northern point of a conically-shaped hill, and its outcrop can be traced for hundreds of feet along the quartzite formation which is largely impregnated with richest mineral in seams and large patches. The ore was found within a foot of the surface on the northern slope of the aforesaid hill, close by huge masses of quartz, which tower several feet above the outline of the hill. It overlies the quartzite in a strata or deposit from three to five feet thick, and of indefinite extent laterally and longitudinally. It has been penetrated by a tunnel 100 feet, running lengthwise in the hill, without discovering its southern boundary, neither has its western boundary been reached, although a drift of 25 feet in extent has been driven across it. Midway from the office of the tunnel, a shaft, or rather incline winze of respectable dimensions, was commenced some days ago. It is now down 65 feet, exposing an immensely rich body of ore, four feet thick between a quartzite foot wall and a porphyry hanging wall. The latter contains large masses of oxide of iron, manganese and talc. The latter has a fine pearly color, is unctuous to the touch, and streaked like marble and looks, when polished, or cut with the knife, exactly like that mineral. Magacian lime is also sometimes mixed with it, but in small bunches generally. The above are about the main facts connected with this wonderful bonanza of ore. The mine is a valuable one and already bids fair to realize the just expectations of its lucky owners. There is considerable ore in sight and the developments that are being vigorously pushed ahead, are bringing to light still larger masses of it. The mine has not been worked much more than 22 days, and yet in that time, there has been not less than \$65,000 to \$75,000 worth of ore extracted from it, that is now piled upon the dump awaiting the packers.

The Gila Company

Was incorporated in San Francisco toward the end of January last, with a capital of \$10,000,000, divided into 100,000 shares, of \$100 each. The incorporators are J. M. English, J. B. McGee, Arthur K. Hawkins, Camille Martin, of the London Chartered Bank, and W. R. Barnes, of Reveille, one of its original owners and locators. The three former gentlemen are co-owners in that other brilliant mining operation known as the Tybo Consolidated S. M. Company (Limited) of London, which I formerly made mention of in the Press. Themselves and the two latter constitute the first Board of Directors, with J. M. English, Esq., President, George E. Clarke, one of the former owners, as Superintendent, and J. A. Knapp, as Secretary, at the San Francisco office. The stock has not been as yet placed upon the Stock Board but will be, most likely, sometime during the ensuing month, in order to afford an opportunity of purchase to the large number of persons, who desire to possess an interest in it. In connection with the property is an excellent

Ten Stamp Mill

In complete running order, lately purchased by the company, and is in thorough repair throughout. This mill was erected here in 1871 by a New York company that subsequently collapsed, after extracting in the neighborhood of \$30,000 in bullion from the ores of the district.

Companies organized in the Excelsior State have never yet done other than the deepest injury to the mining interests of Nevada. Ignominious failures have been the general result of all of their undertakings. Two of them at one time threw a blight upon the mining interests of Eureka. Reveille was the next sufferer and now comes Morey district to appeal to our sympathies and excite our indignation and contempt. The mill is a wet-crusher, and is copiously supplied with water from a neighboring spring. Wood, too, is found within convenient reach, on the eastern slopes of the Diamond range, distant about one and a half miles from the mill. The buildings comprise an office, Superintendent's and Secretary's residence, an assay office, a spacious boarding house, a lodging house, a blacksmith's shop, together with a commodious stable, corral, etc., and all the other appliances. The mill is being overhauled with a view to the immediate resumption of active operations, after its long idleness. The necessary supplies of quicksilver, sulphate of copper, etc., have been already received from San Francisco, and salt, which is the most important element, is found in large quantities at the marshes, a few miles to the east and northwards of here, and it can be laid down at the mill at a cost of about \$40 per ton. The standard of fineness ranges from 70 to 95 per cent of pure chloride of sodium, the residue in soda and insoluble matter. The ore has to be hauled a distance of eight miles, and will cost from \$7 to \$8 per ton, but either of these is a moderate sum enough when the quality of the ore, and stretch to be traversed are taken into account. Hauling commences in a few days, and it is expected that the music of those long dormant stamps will greet our ears sometime about the first proximo, and then add to the general activity and enlivenment of the scene.

From the foregoing sketch, imperfect and all, though it is in character and detail, it will be readily seen under what favorable auspices the Gila company flings its symbolical banner to the not over gentle zephyrs of this long neglected section of the State. Long may it float in triumphant brightness and beauty, the representative of not alone a nation's greatness and glory, but the symbol of corporate honor, energy and enterprise. With such a union, success is the inevitable result. Prosperity is bound to exist wherever nature has laid the foundation as broad and deep as she has here, and its march cannot very well be retarded if there is a reasonable amount of care, economy and judgment exhibited in the management and general direction of affairs. These, however, will not be wanting. The character of the gentlemen at its head, coupled with the discretion and practical experience of its superintendent, are the best guarantees which the public can have of the bona fides of the undertaking. These gentlemen have already purchased the property, and subscribed largely to a fund to meet current expenses.

There are many other deserving mines located here that I cannot at present find time to fittingly describe. Besides, I have only examined a few of them, and since I do not desire to pass aught that cannot be substantiated, I forbear until such time as I can do so with propriety and confidence. The old town of Reveille is once more donning the habiliments of every day life, such as becomes an active, hopeful camp. It contains already a butcher shop, a boarding house, and a commodious store, filled with a large and varied assortment of merchandise, owned by Messrs. Clark & Barnes, who have resided for the past eight years in the district. Excelsior Reveille!

J. D. P.

Reveille, Nye county, Feb. 27th, 1875.

Mammoth District, Nevada.

EDITORS PRESS:—In the language of the immortal Webster, I wish to inform the public through your valuable paper that the old Mammoth district, in Nye county, Nevada, "ain't dead yet." She still lives rich in silver and a fair scattering of gold. Within the last year her mines have been prospected, and such results obtained as to remove all doubts as to their value and permanency. And for the benefit of all whom it may concern, I propose to give a brief sketch of some of the mines now being worked.

The Silver Wave,

Situated half a mile west of the town, has an incline 120 feet, drifted 50 feet north and 25 feet south on the ledge, which is on an average 2 1/2 feet wide producing rich ore. From assays, it goes from \$150 to \$300 to the ton.

The character of the ore is black metal and chloride. There is no waste in the lode; all of it producing good milling ore.

It is a well-defined lode with good hanging walls, and has every indication of a permanent mine. They have from 75 to 100 tons of ore on the dump.

The mine is worked by the owners, all persevering men. Frank McPherson is Superintendent, an energetic man and good miner.

The Empire

Situated about half a mile west of the Silver Wave, has an incline 125 feet, a good track and car, and have struck good ore in the bottom of the incline. They have a ledge about three feet wide, and a splendid prospect. The char-

acter of the ore is the same as the Silver Wave. This work is prosecuted by a Mr. Beon, President of the company in Syracuse, New York, and who is having other mines prospected in the camp under the supervision of a Mr. Rider, a very fine business man and a good miner.

Another Mine

Lying a short distance northeast of the Empire, has an incline about 50 feet, rich ore and a well-defined ledge and a good prospect. The work is being prosecuted by Messrs. Welch & Hawke, both long residents of the camp. Other mines are being prospected not far from this locality by Mr. Downey & Bro. with good encouragement.

Rich Strike.

I wish to make special mention of a mine about 3 1/2 miles west from the town, lying on the west side of the Mammoth range of mountains, a short distance below the Summit, near the head of a large canyon. It was discovered by James K. Evans on August 28th, 1868. It is called the Lisbon. Mr. Evans was formerly an old lumber dealer in California, between Auburn and Illinoistown. Within the last month they have struck the bonanza of this district. Or, as it is said by old miners, they have struck a chimney of ore "bigger than a man can think." It was found by running a tunnel at right angles 250 feet, and they struck the ledge 140 feet below the surface. In addition to this prospecting they came back to the mouth of this tunnel and ran another so as to strike the ledge squarely, and at a distance of 120 feet they struck this body of ore 90 feet below the surface. They are now 16 feet in the ledge, and their tunnel is seven feet high and five feet wide, and they intend to go through it, be the distance what it may. From some half dozen assays that have been made, it goes from \$300 to \$600 per ton. The ores consist mostly of a carbonite with some chloride, resembling the ores found in Cerro Gordo; so it is said by those who have seen both. The ledge so far is soft, so that it can be abstracted with a pick, and two men are now taking out four tons a day. It is thought by experienced miners that the prospect in sight will run a 20-stamp mill right along. A man by the name of Henry Ragins has become half owner in this mine, and he is thought to be the right sort of a man.

Several other mines in this locality show good ore and fair prospects. In addition to these, in another belt only a short distance, is reported to be fine smelting ore, but nothing of this kind having ever been tested here, no definite opinion can be given at this writing.

A short distance north of Mr. Evans' mine, Mr. Crowell is making preparation to prosecute work on the Cadiz mine, which has indications of a large and well-defined ledge.

To return to our little town. It is situated in a beautiful canyon pleasantly located for residents and well supplied with timber and water. We have a ten-stamp mill here and are confidently looking forward to a lively time the coming season. PINE NUT.

Ellsworth, Nevada, Feb. 20.

DISPOSING OF SEWER GAS.—How effectually to get rid of sewer gas is a problem that has long puzzled engineers and sanitarians. Most of the experiments have resulted in failures, and none have thoroughly succeeded, except in making what was a great deal worse. An English inventor has recently patented a new mode of dealing with the gas, which is ingenious and promises to be effective.

Connected with the main sewer is a pipe two inches in diameter, and at the top of the pipe is a ball, so fixed that it allows an aperture of a quarter of an inch all round, through which the sewer-gas may escape from the pipe. Running up outside the large pipe is an ordinary gas-pipe, and underneath the ball at the top of the sewer-pipe a set of burners is so arranged that when lighted they make a complete circle of fire. The ball prevents the sewage-gas from rising through the center, and it cannot escape through the flame, which entirely surrounds the aperture. The invention may be easily applied to the public lamps.

A WIRE TRAMWAY FOR MT. DIABLO.—A company has been formed to build a wire rope tramway—similar to that exhibited at several Mechanics' Fairs in this city—to transport people from the foot of Mt. Vesuvius to its top. The mountain, very properly suggests the *Alta* of this city is about as high as Mt. Diablo, or as the top of Sentinel Dome above Yosemite Valley, and if such an enterprise will pay in Italy, it may be worthy of consideration here, though the tourists who go to Naples probably are a hundred fold more numerous than those who come to California.

THE NEW, OR TOLBUT COAL MINES, near Seattle, are going forward in development. The tunnel is now 420 feet long, and still extending day and night. There are 12 feet of coal in the seam, with a half inch of shale or slate in the center.

PACIFIC COAST WOODS.—A collection of Pacific Coast woods is to be formed at the State University, and tests will be made of their capability and peculiarities. Some useful knowledge may be thus obtained.

MINING has begun on the placers of Santiam, fifteen miles from Smith's Ferry, Oregon.

AN ASBESTOS mine of very fine quality has been discovered near Eureka, Sierra county.

MECHANICAL PROGRESS.

Action of Zinc on Boilers.

Reports have from time to time appeared of late with regard to the usefulness of a piece of zinc in a steam boiler as a preventative against incrustation. Quite a number of engineers have expressed approval of it. Some say they have used it for many years, and that it not only prevents the deposit in the boiler from becoming scaly and adhering, but that it also prevents rust in all the pipes connecting with the boiler, so that in one case where zinc was used the pipes did not want any extraordinary repair in twenty years, while without the use of a piece of zinc in the boiler, they were all leaking in three years, especially at the elbows and T's.

One engineer mentions, to the *Scientific American*, a drawback, namely, the deposit of a material like calamine in the cylinder, piston head and pump, causing them to work badly.

A later correspondent of the same journal, L. T. Wells, of Carondelet, Mo., says: Seven or eight years ago, I tried the experiment, under the idea that an electrical condition might probably have something to do with boiler incrustation. The boiler I had was an upright one. I placed a piece of zinc weighing about two pounds on the dome inside, between the tubes; it remained there about two months, and during that time the boiler was opened at the bottom, on three sides, for a weekly cleaning. I noticed that the mud (Mississippi mud) was quite different from that previously deposited. Before it was mostly made up of scales; but after the zinc was put in, the deposit was soft, and scarcely a sign of scale was visible, the surface of the iron within looking fresh and new.

Notwithstanding this favorable action of zinc, it is not to be recommended for this purpose. I found the cylinder, piston rod and piston head badly incrustated by something which I could not understand; the pump worked badly and frequently failed, becoming incrustated within. I sent it to be repaired to the maker, who on opening it, expressed his surprise at its condition, and said: "How came this stuff on the pump? It looks like calamine." Zinc as a preventative of boiler incrustation will not do; if, however, the zinc produces a galvanic current, and renders the iron negative, then the experiment is suggestive of a principle that can be used by external application of the galvanic force.

Another, writing from Utica, N. Y., alludes to a previous correspondent as follows: I saw in your issue of December 12th, that an engineer on the steamship *St. Laurent*, running between New York and France, had left an ingot of zinc in one of his boilers; and on looking for it at the end of the next trip, he found it all wasted away to a mere mud. This is not new here. Mr. J. J. Illingworth, chief engineer of the Utica Steam Cotton mills, first introduced zinc in their boilers nearly twenty years ago, and by his recommendation it is now used in the New York Mill's boilers and in many boilers and in many other places. Mr. I. claims that the zinc has a great affinity for oxygen, and therefore absorbs the oxide in the water, and thus prevents its affecting the iron of the boiler. I herewith send you a couple of pieces which I obtained from him; and you will see that they are not all gone to mud, as they would have been if they had been left in the boiler a week or two longer. These pieces have been in the boiler about four weeks. In the New York mill where soft water is used, the zinc will lay there without being affected; but as soon as the hard water of the Sangquit creek is used, it begins at once to affect the zinc. Nor is this all of the effect of the zinc in the boilers; it prevents the steam pipes (running round the mill for heating purposes) from rusting.

To show this more conclusively, I will say that the piping in the above mill, where zinc has been so freely used, has been in twenty-five years, and has needed no more than the ordinary repairs that such pipes require. But on the other hand, the company built a new mill (which was started in October, 1869), and, for some reason not explained, there was no zinc put into the new boilers for about three years. The result of this neglect or oversight was that the heating pipes all through the mill began to leak at the elbows, couplings and T's; and on taking the pipe apart for repairs, it was found that wherever the steam struck the T or elbow or dripped into it, there was a hole eaten into it; and when a piece of pipe was to be taken down, there was no telling where the workmen could stop, because the pipes, T's, elbows and couplings were generally eaten away. I also send you a T, which is a fair sample of all the pipe and other joints connected with it.

When this was brought to the knowledge of Mr. I., he began at once to put zinc into the boilers of that mill, and the result of it is that the rusting of the pipes has entirely stopped and the bill of repairs has lessened accordingly. I am told that the above engineer has used zinc in his boiler, for over twenty-five years, with the same result in all cases.

STEEL RAILS.—Steel rails appear to be everywhere exceeding those of iron. All of the contracts lately given out by the Belgian Government for the State lines are steel. It is stated that steel rails are about as cheap now as iron rails were two or three years ago.

Aluminium Utensils.

Seventeen years have passed since Deville first produced aluminium on a commercial scale; but the expectations regarding this very interesting and meritorious invention of the distinguished French chemist have not as yet been fulfilled. Although many of these expectations were somewhat exaggerated, they were not so unreasonable as many people believed them to be; for a metal with so many valuable properties would be useful in many of the technical arts. Among these properties are a beautiful color that does not change in the air, nor yet in sulphurous exhalations, and further, remarkable lightness, an agreeable resonance, and a capability of being worked into any shape. Moreover, in the use or manipulation of aluminium there have not hitherto been observed any deleterious effects.

It is generally conceded that the cost, and not the absence of properties which make other metals valuable, has prevented the more extensive application of aluminium; and the price, although it is considerably less than it was at first, has remained high for many years. The cost of production of this metal, which can only be extracted by the use of sodium, cannot possibly be the only cause of its high price; for the commercial manufacture of sodium may be considered as a solved problem, and, as soda ash is very cheap, sodium might be produced at a moderate cost if the demand were greater than it is. Large production is caused by large consumption, and the use of aluminium has been hitherto limited, mainly because custom and use have in a measure opposed the introduction of such a novelty, except for fancy articles.

Stories have been written and told about poisoning by cooking vessels made of copper, by glazings containing lead, and the formation of verdigris on spoons of (alloyed) silver; but if people were only determined to produce these utensils from aluminium, all danger from poisoning would be removed, and they would have vessels, the appearance and durability of which would leave scarcely anything to desire. They would be more convenient to handle than our light crockery ware, for they can be made as light and, what is important, cannot be broken. Splendid pitchers, plates, goblets, lamps, etc., might be manufactured from deadened and embossed aluminium; and the lightness of spoons of this metal would make them more convenient than those of silver now in use. In this case it is not the price, but only prejudice, which presents itself as a drawback, for the price is only half of that of good silver; beside, the difference in the specific weights of both metals and the consequent cheapness in the use of aluminium are so great that, for the value of one silver spoon, at least even equally large aluminium spoons might be bought. True, aluminium is neither a rare nor a noble metal but it possesses, nevertheless, advantages over alloyed silver which give it a much finer appearance; it does not get black, nor does it form verdigris, and what it lacks in brilliancy and appearance is well compensated for in its agreeable lightness. But, unfortunately it has been found impossible to plate with aluminium either by the galvanic or foil method.

IRON AND STEEL TIRES.—A description is given of an improved method, recently introduced abroad, of reducing the inner diameter of tires which have been unduly enlarged by the hammer or the rolls so that they cannot be put on when hot in the usual manner. This plan consists in heating the tire to redness and then plunging it horizontally, but only to half its breadth, in water, and leaving it there till quite cold. The operation is then repeated in the same position, after which the tire is turned over and the heating and plungings applied to the other half of the ring. The first cooling produces a contraction of which the half not immersed partakes, and thus undergoes a molecular retraction, resulting in a reduction of diameter; of course the same is produced in the other half during the second operation. In this way, it is said, a tire has been reduced 7 in 895; and four immersions will double the shrinking. In the same manner a ring of Bessemer steel, which had not only enlarged under the hammer, but had also become conical in form in the interior, was brought to the exact diameter by heating and immersing thirteen times successively—first, the side which was contracted, and afterwards that which had become enlarged. The correction amounted to nearly four inches, though the diameter of the steel ring is not given.

IRON FURNITURE.—Amongst recent industrial developments in Germany is the hollow iron furniture, which has been popular for years in Austria. In Germany, however, it is only quite lately that the first large factory for making this class of goods has been opened. Ribbon-iron of the best quality is taken and converted into tubing in pieces of about 16 feet long, which can be bent cold into any form suitable for the making of bedsteads, doors, tables, etc. Hollow iron is stronger and lighter than the solid iron usually employed heretofore, and possesses the special advantage that the rivets hold better and that it does not break so easily, as is frequently the case in solid iron, which gives way wherever there is a flaw.

Russia has hit upon the original device of building wooden-clad vessels of war, the outer coating of timber being intended to protect the iron from injury.

GUNPOWDER EXPERIMENTS.—Certain experiments which have been made at the Chemical Department, Royal Arsenal, by Professor Abel and Captain Noble, relative to the properties of gunpowder, have reached a definite stage, and a preliminary report has been made. The objects of the investigation were to ascertain the products of explosion when fired in guns or mines, the tension, the effect of various sized grains, the variation produced by various conditions of pressure, the volume of permanent gas, the heat, and the work performed on a shot in the bore of the gun. For these purposes a steel chamber was used, closed with a screw plug, through which circuit wires were led and the powder fired by electric current. The pressures were registered by crusher gauges, and when the powder fills the space in which it is fired it is found that the pressure is about 6400 atmospheres, or 42 tons per square inch. The temperature of explosion is found to be about 2200 degrees Cent. When gunpowder is fired in small arms, about 35 per cent. of the heat generated is communicated to the barrel, but only 3 per cent. is absorbed by an 18-ton gun. The products of explosion are about fifty-seven parts weight of solid to forty-three parts of permanent gas. The analysis of the gaseous products showed a regular change, due to variation in pressure, carbonic anhydride increasing, with a decrease in carbonic oxide, as the pressure increased. The solid products were subject to greater and less regular variation; generally speaking, the chemical action is more complicated than has been supposed, and the old fundamental equations are found to represent it very imperfectly.

SCIENTIFIC PROGRESS.

ANCIENT AQUEDUCTS.—M. Belgrand, whose services to Paris, as director of the water service of the city cannot be overrated, has made a highly interesting communication to the Academy of Sciences, in the form of an extract from a book which he is about to publish on "Ancient Aqueducts," or the distribution of water in Egypt and Greece. He showed that Egypt never could have had aqueducts, but that her system of irrigating is of the highest antiquity, and still excites the admiration of engineers. With all the engineering art at present existing, says M. Belgrand, it would be difficult to construct covered aqueducts, as the lowest practical fall, namely, 0.10 in 1,000 cannot be obtained. The ancients never made aqueducts with a fall less than 0.50 per 1,000 feet, and no trace of a covered conduit is found in Egypt or in Nubia. Greece was certainly supplied by aqueducts, as their gymnasium supplied the Romans with the type for the Thermes. But the aqueducts of the former were much less important than those of the latter. M. Belgrand intends to complete the history of the aqueducts of the ancient world, and also of those of modern times, down to that of the derivation of the Vannes, which is now approaching completion, and the waters of which will entirely supersede the less wholesome water of the Seine. These scientific histories will form a mass of valuable information, and save water engineers a vast deal of trouble.

THE FREEZING POINT.—Schultz shows that the freezing point of water is lowered by dissolving gases. That water holding solidified freezes at a lower point is well known. Thomson and Clausius have shown from the principles of the mechanical heat that the freezing point of water falls 0.007°C for every additional atmosphere of pressure. To determine the true freezing point, take a glass tube closed at one end, fill with sulphuric acid, and heat. Then pour out, and rinse repeatedly. The tube is then two-thirds filled with distilled water, which has been boiled for some time in a clean heater, and a small quantity of filtered oil of turpentine is poured upon the water. The tube is then carefully heated, without allowing to rise to boiling point, lest an explosion should ensue, to remove any bubbles which may adhere to the side. The tube is taken out of the oil-bath, cooled, and placed in a freezing mixture. In most cases a portion of it freezes at once, if a thermometer is inserted, and moved up and down. If not the tube must be returned to the freezing mixture. It is important that the thermometer should be cooled down to the freezing point before being introduced.

DEATH OF A SCIENTIST.—The death of Chas. Lyell, which took place in London, Feb. 23d, is a great loss to the scientific world. For more than a quarter of a century he had been one of the chief teachers of the age. He gained most of his fame as an author of standard geological works, in which he summed up all the knowledge of the time in a lucid style, and in this manner he did much to popularize one of the most important branches of science. His last notable book was on the antiquity of mankind. He was a man of liberal and advanced ideas, and was always ready to grapple with any question which came up within the legitimate field of scientific research. He was progressive to the last.

MEDAL AWARDS.—The Copley medal of the Royal Society has been awarded to Prof. Louis Pasteur "for his researches on Fermentation and Pebrine," and the Rumford medal to J. Norman Lockyer "for his spectroscopic researches on the Sun and on the Chemical elements."

An Interesting Solution.

Among scientific puzzles is one which has long perplexed geologists, viz., the existence of large areas of rock containing no sign of life, aside by side with formations of the same period which are full of fossils—relics of primeval life. Why should one be so barren, and the other so prolific? There is now an answer in this important question, and readers who take an interest in the exploring voyage of the "Challenger" will be glad to learn that the answer comes from that ship, in a paper written by Dr. Wyville Thomson, chief of the scientific staff on board. This paper was recently read before the English Royal Society, and contains the result of some deep sea-sounding, which have revealed the existence of vast areas of barren clay at the bottom of the bottom of the sea, in depths varying from 2,200 to 4,000 fathoms and more. In parts the bottom is composed of the so-called *globigerina* mud; that is a thick deposit of small creatures known to naturalists as *globigerina*, which live near the surface and sink to the bottom when dead. There they accumulate, building up chalk for ages to come, when land and sea shall once more change places.

But it is remarkable that at the depth of 2,200 fathoms the *globigerina* then often disappear, and the gray deposit merges into the barren clay above mentioned. The explanation is that below the 2,000 fathoms these tiny shells are dissolved by some action of the water, and that the minute quality of alumina and iron which they contain go to form the areas of barren clay. The extent of these areas is so great that it exceeds all others as yet known at the bottom of the sea, and it is also the most devoid of life. In this respect the red clay now forming, resembles the schist which at present occupies so large a part of our earth's surface. We are all more or less familiar with chalk and with rocks that show no sign of fossils; and to be thus, so to speak, made eye-witnesses of the process by which chalk and rock were formed is unusually interesting. Dr. Thomson's paper is published at length in the *Proceedings of the Royal Society*. Its importance may be judged of by the fact that one of our most eminent naturalists declares that it alone is worth all the cost of the "Challenger" expedition.—*Chambers' Journal*.

A NEW LIGHT.—A new artificial light of great intensity, particularly rich in photographic rays has been recently invented in France. A quart bottle with a somewhat large mouth, has a cork with two openings. Through one of these a tube passes to near the bottom of the bottle; through the second a large tube packed with iron scale issues. Fragments of pumice fill the bottle, and on these carbon disulphide is poured. A current of nitric oxide gas, prepared by Deville's method—by the action of nitric and sulphuric acids on metallic iron contained in a self-regulating reservoir—is passed through the bottle, where it takes up the vapor of the disulphide. It is then led through the safety-tube packed with iron scale to the burner. Excellent photographs were taken in five seconds with this light, the object being six feet distant. In photographic power the light is asserted to be superior to the magnesium or calcium light, and even to surpass the electric light itself. The products of combustion are noxious and must be gotten rid of.

ENCKE'S COMET.—The return of Encke's comet to our heavens has been for some time expected, but its immense distance (182,000,000 miles) rendered all search with ordinary instruments needless. The large equatorial at the naval observatory, Washington, D. C., was recently put into service, and the comet was seen through this superb instrument by Professor Holden and Paymaster Tuttle of the U. S. N. Its distance rendered the use of the micrometer impossible, and it will scarcely be observable under ordinary circumstances for several weeks.

It is known to our readers that the equatorial telescope above mentioned is one of the finest in the world. It is Alvan Clark's masterpiece, and has an objective 26 inches in diameter. Its power is now demonstrated in a remarkable manner.

A MATCH UNDER THE MICROSCOPE.—Those who are fond of investigations with the microscope will find a beautiful object in the head of a parlor match. Strike the match, and blow it out as soon as the head has fused sufficiently to cause protruberances to form on it; on the part of the head which took fire first, will be found a white, spongy formation, which, under the microscope and with a bright sunlight upon it, has the appearance of diamonds, crystals, snow, frost, ice, silver and jet, no two matches giving the same combination or arrangement.

PYROMETER.—Pyrometers are rapidly approaching a very satisfactory degree of perfection. It appears from a report of a committee of the British Association of Science charged with examination of the above instrument, that, by means of the Siemens electric pyrometer, changes of resistance amounting to about 1-10,000 of the quantity of heat to be measured can be detected without much difficulty.

OBTAINING OXYGEN.—In the establishment of Krebs, Kron & Co., Berlin, oxygen is prepared by heating together in a glass flask, in a water bath, 10 quarts of water, 10 lb chloride of lime, and 1 lb nitrate of copper. It produces 15 cubic feet of oxygen.

Work Done with Burleigh Drills.

Since the introduction of Burleigh drills and air compressing machinery on this coast, about two years ago, it has accomplished feats which were deemed impossible. In tunneling work especially it has been of immense advantage, and has enabled mining companies using it to double the work at a great reduction of expense. Of late it is being used extensively in the gravel mines, where a great amount of tunnel work is often necessary. This Burleigh drill is in use at the Golden Star mine, and has given great satisfaction. We append a letter from the Secretary of this company to the agents of the drill in this city, which, as it gives details of cost and work accomplished, is of interest to the mining community:

OFFICE OF GOLDEN STAR M. Co. }
Sacramento, March 8, 1875.

MESSE, PARKS & LACY—Agents Burleigh Drill Machinery—GENTLEMEN: For the information of those engaged in mining, and who may be contemplating the purchase of your machinery, the directors of our company have instructed me to state that the drill, with necessary propelling power and connections was placed in our mine and commenced work about the 1st of December last. The material is hard cement with cobble intermingled, and working with the ordinary hand drill three shifts would make about two feet per day, costing us from \$12 to \$15 per foot to run the tunnel, which is 7x7. With this machinery we make from five to six feet per day—at a cost of from \$6 to \$7 per foot.

During the three months or more use of the machinery there have been no breakages or repairs worth mentioning.

Annexed is a report of the actual working of the drill for the 22 days comprising the month of February. It is deemed proper to add that the cost of the machinery complete, set up and at work at our mine has been \$4,500, and this includes column, drills, extra parts, 2,000 feet of ten inch iron pipe, asphaltum coated, air tanks, air compressor and 15 horse-power boiler—original purchase money and placing and housing the machinery.

Report of working Burleigh drill machinery for 22 working days of February, 1875, at Golden Star tunnel, Sierra county Cal.

Size of Tunnel.....7x7
No. of one and three-fourth inch holes drilled.....688
Aggregate length of holes.....2,433 feet
Average depth of hole.....3 feet 6 inches
Consumption of wood per day.....75 pounds
Steam and air pressure.....75 pounds
Lubricants—43 gallons oil 10 pounds tallow; one pound black lead. No repairs.

The entire expenses for the month cannot vary much from \$700 or about \$6 per foot for the tunnel actually made.

Given under the seal of said company, by order of the Trustees.

L. UREN E. CRANE, Sec'y.

Determinative Mineralogy.

We have received from A. Roman & Co. a copy of the "Manual of Determinative Mineralogy," with an introduction in blow pipe analysis by George T. Brush, Professor of Mineralogy in the Sheffield Scientific School. The material in the compilation was, for the greater part, prepared almost twenty years since, by Prof. S. W. Johnson and Prof. Brush as a text book for students in the laboratory. It was not then published but has since served as the basis of a course of lectures and practical exercises annually given in the Sheffield laboratory. The tables presented are based on the tenth German edition of Von Kobell's book. Additions of new species have been made, and in many cases fuller details are given in regard to the old species, and the whole material has been thrown into an entirely new shape. Berzelius and Plattner are the main authorities quoted in the chapters on blow pipe analysis. In determinative mineralogy, heideka the works of Von Kobell, free use has been made of the treatises of Naumann and Dana.

The author states that it is proposed at some future time to add to the volume methods for the determination of minerals by their physical characteristics. The whole work is an invaluable one to the student of mineralogy, and the tables render it useful for regular laboratory work. It is the most complete work on the subject we have seen, the tables particularly being voluminous and well arranged. The first chapter is taken up with a description of the blow pipe and its uses, with list of articles used, reagents, etc. Then a systematic course of qualitative blow pipe analysis is set forth. Then a table showing the behavior of the earth's and metallic oxides before the blow pipe. There is given a very excellent and complete alphabetical list of elements and characteristic blow pipe with other reactions. Chapter 4, gives tables for the determination of mineral species by means of simple chemical experiments in the wet and dry way, translated from Kobell's *Tafeln zur Bestimmung der Mineralien*. An entirely different mode of arrangement, however, is given with much additional matter. The book is really a valuable one for reference or for the student.

The work of repairing the break in the little tunnel through White's Hill, on the line of the Marin narrow gauge railroad was completed last week.

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.

THE White Pine News of the 6th inst. contains the following Mineral City items: We learn from Fred Hill, Esq., that the mill of the Watson company is running finely, and that the new concentrator are working beyond the expectations of the company. The mill is running on old tailings with complete success. Judge Walsh, Superintendent of the Canton company's property, will start up the furnaces about the 6th of the present month. Owing to the satisfactory manner that the Superintendent has handled the property of this company, they propose to back him in all his undertakings, and make times lively in Mineral City the coming summer.

THE Eureka Sentinel states that the Eureka Consolidated company has a splendid body of high grade ore near the northwesterly end of the Champion mine. Four years ago it was supposed that this part of Ruby hill had been worked out; but it appears now that effective work was all that was required to bring new bodies of ore into sight.

OVER 100,000 cords of wood, awaiting shipment to Virginia City and Gold Hill, are piled up in the vicinity of Empire city. Nut-pine wood is being shipped from the same locality at the rate of about 400 cords per month. It can be laid down in Virginia city by the car load for about \$15 per cord.

THE Blue Gravel mining company at Sucker Flat, in a late clean-up, realized from \$130,000 to \$140,000.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

E. DORADO QUICKSILVER M. Co. March 8.—Location: Agre Mining District, El Dorado county. Directors—S. B. Martin, Julius Bandman, D. R. McKillican, S. A. Lane and Jacob Greenbaum. Capital stock, \$10,000,000, in 100,000 shares.

CAROLINA MINING Co. March 9. Location: Washoe. Capital stock, \$7,800,000. Directors—A. C. Taylor, O. R. Johnson, H. S. Wheeler, C. A. Larkey and P. F. McWhorter.

FORT MILLER GRAVEL M. Co. March 9. Location: Fresno county, Cal. Capital stock, \$2,500,000. Directors—Warren Bryant, P. J. Galpin, W. K. Doherty, T. O. Carter and J. T. Earnest.

RED MOUNTAIN QUICKSILVER M. Co. March 9. Location: Stanislaus and Santa Clara Counties, Cal. Capital stock, \$5,000,000. Directors, W. G. Hughes, Win. Muir, J. W. Bond and S. P. Sampson.

SAN JOAQUIN AND FRESNO WATER Co. Mar. 10.—Object: The construction and maintenance of a canal and other works, to divert 30,000 inches, more or less, of the running waters flowing into the San Joaquin river, at and near a point in said river designated by a claim of said waters made by Warren Bryant, T. O. Carter and others, on or about the 10th day of February, 1875, as by the notice of such claim, duly made and recorded, will fully appear; and also to make use of said waters for the purposes of agriculture, transportation and mining, and all other purposes incident to or connected with any of said purposes, and to carry and convey the waters in and through the counties of Fresno, Merced, Stanislaus, San Joaquin and Contra Costa, from said point of diversion in, upon and along the lands where the main conduit of said waters claimed and diverted may be made to reach, by means of branch or side conduits of any kind hereafter constructed or laid down, and connected with said main conduit; also to lease, sell and convey rights to use said waters so diverted, for any of the purposes named. Trustees—Warren Bryant, P. J. Galpin, W. H. Doherty, T. O. Carter and J. T. Earnest. Capital stock, \$10,000,000, divided into 100,000 shares.

Mining Stocks.

After a depression of several weeks the stock market has again commenced to show some signs of activity. On Monday, on receiving news of a strike in Ophir, the whole line of the Comstocks went up. It has been expected for some time that as soon as a strike was made it would enliven the whole market. Outsiders were looking with some degree of certainty to a "deal" in Idaho and Ely stocks. In certain measure their expectations have been realized, as Raymond & Ely and some other of the Pioche stocks have experienced a considerable rise. The Idaho stocks, however, remain as of yore. Golden Chariot has had an assessment levied on it, and if the usual tactics of the ring having this line of stocks in tow are carried out, the whole list will shortly have an assessment on them. The idea is now that some of these mines are looking better than they should for the interests of the manipulators, and they want to assess them down out of sight and then buy them up. If these tactics are carried out, in about two months people will have a chance to invest in Idaho stocks at high prices, for the ring will run them up if they buy them in cheap. However, forewarned is forearmed. What is to be done in the Ely stocks is as yet uncertain, but most people predict a rise.

Of the Ophir strike the *Enterprise* says: "In the Ophir the drift from the bottom of the north winze had last evening been extended twelve feet, all the way in a mass of chloride and sulphureous ores of the richest description. This development is of great importance in many respects, and is therefore attracting much attention. Although they are as yet into the new body but twelve feet, there are certain indications which make it the best strike yet made in the mine. First, the dip is to the east; and, second, there is water in the ore. The trouble was in the bodies of ore found above that they were all too dry. Rich as they were there was a lack of moisture about them that made old miners distrust their permanency. The new body fulfills all of the conditions. It is as rich as could be desired; dips in the right direction and is wet. The fact of there being water in the ore on the 1600-ft level shows that no drift, crosscut, or other opening yet made on the 1700-ft level has passed into or through the same streak of rock. It is quite certain that this body of ore will be found on the 1700-ft level, and at no distant day. The finding of this body in no way interferes with or lessens the prospects in other parts of the mine.

A thing to be noted, too, is the "making to the north" of all the ore-bodies found in the Ophir. In all we have ever had to say of the mine, this peculiarity of the ore-bodies has always been prominent. From the first striking of ore in the mine up to the present day, this making to the north has been the main feature. What it portends we know not; but every body of ore found in the mine has been richer and stronger on the north side. The same is the case with the body just being opened on the 1600-foot level. It appears to be in the opinion of Superintendent Curtis, but the tail end of a very heavy body of ore lying off to the north, the head of which he thinks is somewhere in the Mexican. This is comfort to the holders of Mexican. There is more comfort for them in the fact of all bodies of ore yet found in the Ophir being decidedly stronger on the north side."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

CALAVERAS COUNTY.

CHAMPION MINE.—**WEST POINT.**—*Calaveras Citizen*, March 6: During the past week sinking has been vigorously prosecuted, developing a third vein running parallel to the north and south lode, and a quality of ore equally good as either of the other two. Practical miners claim that this, so far, is one of the richest mines in the State. The rock has never paid less than \$100 to the ton, and as high as \$500, the rock now not being placed at the latter figure. If the mine holds good along this north and south vein, as indicated by surface prospecting, properly opened, it could be made to yield from fifty to sixty tons per day, and, taking an average of the rock already crushed, it can readily be seen what a valuable piece of property Mossers, Haskins and Hadley have come into possession of. With proper machinery, and this mine thoroughly opened, it could be made the most productive ledge in California.

COLUSA COUNTY.

A SINGULAR LEDGE.—*Colusa Sun*, March 6: There has been a company at work on the ledge near Founts' Springs, heretofore noticed by us as containing a kind of white metal supposed to be tin, and which assays both gold and silver, and they have in running the tunnel found almost everything. They have good prospects of cinnabar, have found several small veins of coal; and the other day they came on a large deposit of shale, so rich in oil that they were enabled to get twenty gallons of oil from a ton of it, and the shale burns as well as coal. The ledge is well defined for miles, and is about one hundred and fifty feet wide, and a very large percentage of the entire mass is metal of some kind. Gold, silver, copper, tin, iron, lead, quicksilver, coal and coal oil have been found in it so far, and the company are now hunting for something else! The tunnel being run will strike the ledge about one hundred and fifty feet below the surface, and the last we heard from it, they were within about twenty feet of the ledge.

CONTRA COSTA.

MINING ITEMS.—*Contra Costa Gazette*, Mar. 6: The work of the quicksilver mining company near Clayton, is being prosecuted with much energy and method. The furnace was put to test for smelting, and was found to require some alteration; but the yield from the ore is quite satisfactory, though only that of the lowest grade was smelted. The prospects are so fair that the company will erect another furnace, and make further preparation for extending their operations.

The company, composed of Charles P. Marsh, Sheriff Morse, and other Oaklanders, who lately purchased the old Lyman Hastings ranch, have done some service prospecting, and propose shortly to engage in testing their ground systematically. Many mining experts and capitalists have visited the district recently, and there is likely to be considerable exploration there for quicksilver this season.

Messrs. Hatch & Co., the present owners of the Heston ranch, north of the Telegraph road, are running a tunnel which at 1,000 feet is expected to strike the coal vein, which has heretofore been somewhat extensively prospected at or near the outcrop. The tunnel is now in 400 feet. Messrs. Lux & Miller, who have purchased the Grover ranch, further down the creek, and adjoining the property of Hatch & Co., are also intending to run a tunnel for the coal vein.

INYO.

PANAMINT DISTRICT.—*Panamint News*, Mar. 6: Prospectors who have come in within the last few days bring with them exceedingly rich rock from all sections—east, west, north and south. They are highly elated, and say that the country hasn't been prospected at all yet. Most all that have been out heretofore seemed to be looking for the high-stained ore, and have passed entirely over the best kinds of free-milling ore. They are just beginning to find out where the best ores are, so they say. The ores we have now are certainly high grade enough to satisfy almost anybody, and if this thing keeps on we advise our dealers in that line to send for more lumber, and our merchants to hurry along more grub.

CONCENTRATORS.—The Herdy concentrators for the Jacob's mill, Panamint, have arrived. They have been placed in position, the pans set, and the mill is ready to start up. Six of these concentrators have also arrived for the upper or twenty-stamp mill of this company, and will be set in operation as soon as the mill is ready to crush the ore.

LAKE COUNTY.

QUICKSILVER SHIPMENTS.—*The Free Press* says that the Great Western and Sulphur Banks mines, both in Lake county, shipped, via Calistoga, on the 25th February, 302 flasks of quicksilver, valued at \$40,000, the product of one week's run.

ANOTHER FURNACE.—*The Bee* of March 4th says: The California Borax Company intend putting up immediately another furnace at the Sulphur Banks Quicksilver mine. The new furnaces will be of the Knox & Osborne pattern, of thirty-ton capacity, with sixteen condensers of the largest size.

NEVADA COUNTY.

NEW YORK HILL.—*Foothill Tidings*, March 7: New York Hill is fast gaining position among our paying mines. Since September last, 315 loads of rock therefrom have been worked at the Larimer mill, which produces something over \$28,000, or an average of \$90 per load. Each month's run has exceeded this previous one in the average value of the rock and when the mine is opened so as to work a reasonable force thereon something weighty in the way of gold bars may be expected.

SIERRA COUNTY.

NEW HILL.—*Mt. Messenger*, March 6: The Oro Q. M. Company have made all arrangements for erecting a ten-stamp mill to work their ore. The surveys for water have been made and plans for the mill about completed. The water will be taken out of the South Fork, and conveyed by flume through a tunnel to mill sight at the lower end of Durgan Flat. It will have a fall of twenty-five feet, which will be ample for the center-discharge wheel they propose to put in. Work will be commenced in a short time.

SONOMA.

RICH STRIKE.—*Sonoma Democrat*, Mar. 6: A rich deposit of cinnabar has been found next to the Sulphur Banks, similar in character to that being worked at the above-mentioned mine. The ground has been located by Jake Gear, the discoverer, Robert Oliver, J. H. Jameson and Geo. Marshall. Mr. A. Miller has located the first extension west, on north side of the road leading from Lower Lake. The prospect in this claim is unusually flattering, and there is considerable excitement in the neighborhood. Two miles west of this, in McIntyre's cañon, T. F. Hayter, Jake Gear and others have made locations. The prospect is same as next to Sulphur Banks.

PINE MINING DISTRICT.—*Sonoma Democrat*, Feb. 27: The recent mineral discoveries between Forrestville and Russian river have led to the formation of a new mining district, bounded as follows: Commencing at John Bone's place, thence running west to Dutch Bill creek, thence down Dutch Bill creek to Russian river, up Russian river to the mouth of Green Valley creek, up said creek to the township line, thence south to the place of beginning. Mr. James Stone, a resident of Redwood township, is running a tunnel on a claim located by him at the head of Duval creek. Some of the rock was sent to San Francisco for assay, and the returns showed \$50 gold and \$6 silver. Some rock from the same claim made a handsome return in quicksilver. Mr. Stone calls his mine the Mountain View. The outcrop was discovered near the top of the mountain, and the tunnel now being run is on the side of the hill below, and will strike the ledge at a considerable depth. Mr. H. Lindolph, residing in this district, is also working a claim which promises a handsome return. There will be great activity in prospecting throughout the county the present season, and we look for the development of rich mines in both gold and silver. Quicksilver is already among our most valuable exports.

TUOLUMNE.

GEM G. & S. M. Co.—*Stockton Independent*, Mar. 4: The mine of this company is located in Tuolumne county, and the principal place of business is in this city. The mine is situated two and a half miles northwest of Columbia, on the Pandole road, leading from Gold Springs to Vallecito. The shaft is 118 feet deep; the north drift 32 feet; and the south drift 20 feet. There are 275 tons of ore on the dump, from which two assays have been made—one of \$132.43, and the other \$136.36. Forty feet below the shaft is a stream of water sufficient to run a twenty-stamp mill. A wheel has been erected, with a pump attached, which will pump the mine dry in one and one-half hours. A drum has also been placed in position at the main shaft which is calculated to raise seven hundred pounds of rock at a time. In developing the mine this sum of five thousand dollars has been expended.

Nevada.

WASHOE DISTRICT.

CALCEDONIA.—*Gold Hill News*, March 4: The repairs to the shaft and machinery are about completed, preparatory to commencing the sinking of the main incline in good earnest. A road has been surveyed from the railroad to the site of the intended new shaft of the company. This shaft will be located on the west side of Gold canyon, nearly on a north and south line with the new Overman shaft, about 1,500 feet south of it and nearly 2,000 feet east of this present hoisting works. The grading for the site has already been commenced, and the most of the machinery is already manufactured at the foundries in San Francisco, ready for shipment. These works will be furnished with hoisting and pumping machinery of the most powerful and approved description, capable of sinking the shaft to the depth of 4,000 feet or more. The shaft will be complete in all its appointments, and is calculated to cut the ledge at a depth of 3,500 feet from the surface.

ORPH.—Daily yield, 150 tons of ore. The ore stops and breasts on both the 1300 and 1465 ft levels, are looking well and yielding the usual amount of good ore. The north winze is down to the 1600-ft level the entire distance in splendid ore. At that point the sinking has been discontinued pending the putting in of station sets at both the 1500 and 1600-ft levels, preparatory to starting drifts west at those points to connect with corresponding drifts from the 1500 and 1600-ft stations in the shaft. These drifts are very im-

portant workings, as they will in a great measure determine the width and character of the ore body at those points, and perhaps set at rest all doubts or cavil in regard to the extent of the paying body of ore in a downward direction. The ore developments already made at the 1600-ft level are acknowledged to be the deepest yet made on the Comstock, being 123 feet deeper than the winze sunk below the 1550-ft level of the Consolidated Virginia.

CONSOLIDATED VIRGINIA.—Daily yield 450 tons of ore, keeping the mills steadily running. The ore breasts are all looking splendidly, as usual. But little ore has been taken from the 1550-ft level during the past week, owing to inability to hoist through the Gould & Curry shaft. On the 1500-ft level the ore stops are being gradually extended north of cross-cut No. 1, along the east wall of the ledge, the ore still continuing of the same rich character. The 1300, 1400 and 1500-ft levels are all being rapidly connected at available points by air winzes, which greatly facilitate the extraction of the ores on these levels. The yield of bullion for the present month up to last evening, was \$763,980.77. The mines never looked more prosperous or promised richer future results than it does at present.

LADY BRYAN.—The body of ore struck in the southeast cross-cut and the south drift on the 80-ft level, still continues to the southward, and is of a very fine and promising character. This ore body has been penetrated by the cross-cut east a distance of 34 feet; and by the south drift a distance of 22 feet, and is of a very even and encouraging character. An average of the thirty-five assays gave \$168.29 per ton. The assays show an average value of about one-third gold to two-thirds silver. On the 250-ft level the west cross-cut has penetrated the ore vein a distance of 40 feet, but has not yet reached the point at which it is expected to find the ore body struck on the level above.

CALIFORNIA.—The north drift of the 1550-ft level is being steadily extended northward at the rate of 25 feet per week, the face of the drift still in ore of the richest possible character. On the 1500-ft level the north drift from cross-cut No. 1 has reached the line of cross-cut No. 2, and a drift has been started back west to meet and connect with cross-cut No. 2. The ore in the west drift and also of cross-cut No. 2 is of a very rich character. The face of cross-cut No. 3 on this level continues in ore of a good quality. The face of cross-cut No. 4 on the 1500-ft level is in 70 feet from the starting point, and is in ore assaying from \$20 to \$30 per ton. The south drift from the east winze, now being sunk from the 1400 to the 1500-ft levels, is still in fine ore. Sinking this winze is also making fair headway, the bottom still in good ore.

SIERRA NEVADA.—The rock in the bottom of the new shaft is much firmer than heretofore, and admits of better headway in sinking than for some time past. The flow of water does not in the least impede progress. The prospecting drifts south from the old Sierra Nevada tunnel are also being driven ahead with all the vigor possible, to reach and determine the character of the ore vein further to the southward than it has yet been prospected on that level.

KNICKERBOCKER.—The west cross-cuts, on both the 600 and 700-ft levels, have struck the east clay wall of the ledge, so that it cannot now be long before the ore vein will be reached on those levels. The new pumping machinery has arrived at the mine, and is being placed in position.

BELCHER.—The ore breasts are yielding the usual amount of milling ore. There is little or no change in any of the ore producing sections during the past week. Sinking the three prospecting winzes below the 1400-ft level still goes vigorously on, the bottom of each still in ore.

NACARA.—The main incline is down 150 feet in depth, and is well timbered throughout. It is being sunk directly on the ore body, which is looking finely, and promises a good development for the future.

SENATOR.—Both main drifts, north and south, are making excellent progress. The south drift, which gives the most favorable assays, is now in 55 feet, and, being in the most favorable looking formation of the eastern Comstock, bids fair from the present showing to soon run into good paying ore.

BEST AND BELCHER.—The south drift, from the double incline winze on the 1700-ft level, is still pushed ahead, following the east clay wall of the ledges. Wherever the east clay wall has been out, it looks very favorable for future ore developments.

BULLION.—Driving the south drift on the 800-ft level is making fine progress. Cross-cutting this portion may yet develop some good ore deposits.

BALTIMORE CONSOLIDATED.—Erecting the new pumping machinery is making steady headway. Prospecting the 750 and 850-ft levels still continues without abatement, and with some very favorable indications of future ore developments.

MEXICAN.—The north drift on the 1465-ft level of the Ophir is showing a steady improvement as the work advances.

ORIGINAL GOLD HILL.—The face of the raise above the 340-ft level, 350 feet south of the shaft, was run six or seven feet into the red ore described in last week's report, and, finding that it was evidently a large and permanent body, assaying high figures, the unsprinkled thought best to get after it in a more practical and efficient manner, as this prospecting raise was in wet ground liable to cave, and noways advantageous to work through. A drift is now being run from the track floor level of the main

south drift, to run under where this ore body is found, and no doubt directly into it. It will be reached very shortly, when a valuable development may be looked for.

THOX CONSOLIDATED.—The new steam hoisting machinery, including an engine (125-horse power), is on the way from San Francisco, and will arrive here on Saturday next.

KOSSTUN.—Sinking the main shaft is making steady progress, the bottom in hard blasting rock. It is now down 450 ft. It is the intention to open another station at the 500-ft level.

JUSTICE.—The prospecting operations on the lower levels are still being pushed ahead with all the vigor possible, the evidences of finding a paying mine becoming more favorable every day.

PHIL. SHERIDAN.—Main west drift going ahead lively, running at present in soft ledge matter, with occasional seams of red quartz from three to six inches wide. These seams or "feeders" assay lightly in gold and are very liable to lead into something good before long.

CROWN POINT.—Daily yield, 400 tons of ore. The ore breasts show but little change during the week. The main east drift on the 1600-ft level to cut and prospect the ore vein at that point, is making steady progress without change of interest to report.

EUROPA.—The face of the east drift or cross-cut from the bottom of the winze, 115 feet below the adit level, shows stringers of very favorable looking quartz carrying metal, and from present indications, as well as what is already known by developments above, the ledge is only a few feet distant.

WELLS-FAROO.—The new steam hoisting machinery which started up ten days since, is now being run day and night, three shifts of miners being employed in sinking the shaft.

GOULD & CURRY.—Rapid progress is being made with the enlarging of the main shaft below the seventh station level.

IMPERIAL EMPIRE.—Sinking the main incline below the 2000-ft level is making good headway. Driving the main south drift on the 2000-ft level is also making good progress.

JULIA.—The face of the main south drift on the 1000-ft level is still in vein matter of a very encouraging character.

OVERMAN.—Steady headway is being made draining the water from the shaft. Arrangements are being rapidly completed for the erection of a more powerful pump for draining the water.

AMERICAN FLAT.—Prospecting the 750 and 800-ft levels is progressing well, with some very favorable indications of ore developments ahead.

SOUTH COMSTOCK.—The new steam hoisting works went into full working operation day before yesterday, and sinking the shaft is resumed under the most favorable auspices.

SILVER HILL.—The face of the south drift at the third station level is still in red quartz of a promising character.

LEVIATHAN.—The new hoisting works machinery has been started up and is getting into full operation to-day.

Colorado.

CLEAR CREEK COUNTY.

SACO.—About 300 feet of the second pocket have been uncovered in this mine.

POLAR STAR.—This mine has been sold at satisfactory prices.

BROOKLYN.—The Georgetown *Miner* says that this mine is rapidly looming into notice, not only as an ore producer, but as a producer of rich ore. It is now being worked by a tunnel or adit on the vein, just above timber line, which has been driven a distance of two hundred feet, reaching a depth of one hundred feet from the surface. The mineral streak varies from one inch to twelve inches, and the ore runs uniformly rich, mill runs giving five hundred and eighty ounces silver per ton for first-class, and two hundred and forty-two ounces for second-class, or a coin value respectively of \$754 and \$314.60.

THE FREN ROSSERS.—This popular mine is, we learn from the *Miner*, being successfully worked. The ore is divided into three classes—first, second and third. The third-class usually runs from 150 to 200 ounces silver per ton, the second-class from 200 to 300 and 400 ounces, while the first-class includes all above that, up to and into several mill runs, above 1,500 ounces.

COLORADO CENTRAL.—A highly interesting fact has been developed in the workings on the ground of the Colorado central, west of the discovery shaft. Here may be seen the phenomenon of a vein of obsidian, volcanic glass, three feet wide, crossing this great ore channel. The obsidian cuts off the vein matter at its crossing with mathematical precision. The ground on that portion of the mine, No. 5, owned by the Marshall silver mining company is now in royal pay. Six different companies who are leasing ground on No. 5, are taking out high grade milling ore in paying quantities and we learn that portions of the ground on the Colorado central is in good pay also.

THE O K—O K is one of the remarkable ore channels of Leavenworth mountain. The ore mined out of this lode has frequently yielded by mill run from 500 to 800 ounces in silver per ton, or a coin value of \$600 to \$1,040 per ton. The total production of this mine has been estimated from \$33,000 to \$40,000. So says a correspondent of the *Miner*.

SACO.—The records of this mine show that the total products since its discovery, two years and six months since, has been \$134,175. The highest mill run of ore taken from this mine, was \$2,900, coin value per ton.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Sixth Lecture Delivered before the University of California College of Agriculture, on Tuesday, January 26th, by PROF. C. E. BESSEY.

[From Pacific Rural Press.]

The Cone Bearing Plants and the Oak Family.

The cone bearing plants, *Coniferae* form a small order of about 350 species. All are woody, varying in size from trailing shrubs to the largest trees on the globe. A balsamic fragrance pervades the family and this is often associated with valuable medicinal properties. In their distribution, they extend throughout all parts of the temperate and colder climates; occurring also to some extent in the tropics, upon mountain sides. They are of great economic importance, furnishing not only the most important woods for lumber, but also fuel, medicines, materials used in the arts and for the people in certain limited districts a considerable amount of food. In the northern hemisphere, the genus *Pinus* seems to be the predominant one in this order and in every country of this half of the globe, one or more species seem to be particularly adapted to meet the wants of civilized man. Of these, we can notice but a few.

The Scotch Fir, *Pinus sylvestris*, is found in Europe and northern Asia, forming large forests. It is very largely used for building purposes. The one referred to in English books takes the place of, or corresponds to the Redwood of California.

White Pine, *Pinus strobus*, is a tall, large tree found growing throughout the northern United States. Its wood is white and it readily works into valuable lumber. It is very largely used, almost to the exclusion of other woods.

Sugar Pine, *P. Lambertiana*, is an enormous tree of the Pacific slope, attaining sometimes the height of 300 feet, with a diameter of 20 feet. It is very similar to the White Pine of the East, but has a smaller cone. The wood is extensively introduced into our markets.

Yellow Pine, *P. ponderosa*, of the southwestern United States, has a dense, heavy wood that almost sinks in water and is full of resin. From the wood of this tree, by burning it with a close, smothering heat, tar is obtained. Pitch is the evaporated tar. Turpentine is a fluid obtained by making rude incisions in the bark of the tree, from which it flows. It is composed of a volatile oil and a resin. When heat is applied, the oil is driven off into a receptacle and is known as this oil of turpentine, while the residue is the well known resin, or rosin, of commerce. Another variety of Yellow Pine, *P. ponderosa*, as also the Western Balsam Fir, *Abies grandis*; Menzies Spruce, *A. Menziesii*; *Thuja gigantea* and Californian White Cedar, *Libocedrus decurrens*, are all of more or less value.

Douglas Spruce, *Abies Douglasii*, of the Rocky mountains and Sierra Nevada region; in some localities is incorrectly called White Pine. It is a large tree, of great height but slender stem, and its wood is largely used for planing, also for railroad ties, for which purpose its great durability admirably fits it. From it very good lumber is obtained, but not the very best. It lasts well, especially that taken from high regions. The tree has a peculiar cone.

The Redwood of the Pacific slope, *Sequoia sempervirens*. A large tree, sometimes attaining a height of 300 feet with a diameter of 15 feet. It has small cones; from one to two inches long, and short leaves which have somewhat the appearance of those of *Abies*. This wood, (Redwood) is the one used more largely in housebuilding. The receipts of this lumber in San Francisco, in 1874, amounting to about 87,000,000 feet, were fully two-thirds of the whole. Spruce fir, *Abies excelsa*, a fine tree, growing to the height of 100 to 150 feet in its European home. From its white deal lumber is made; from its resinous juice, Burgundy pitch is made and its branches are holed to aid in the manufacture of spruce beer.

Balsam Fir, *Abies balsamea*, a native of North America, is a fine tree of small size. It produces a turpentine known as Canada balsam, used in mounting microscopic objects.

The European Larch, *Larix Europaea*; is, in England and Europe generally, a valuable timber tree. From its juice is obtained Venice turpentine. This tree is also grown for ornamental purposes. *Cupressus*; valuable trees, known as Cedars. Their wood is very durable and is largely used in the manufacture of various domestic utensils, as well as for posts, piles, etc. Some of this species are used for ornamental purposes among which may be mentioned the Monterey cypress.

The Junipers and Red Cedars, *Juniperus*, are valuable for their durable wood. From *J. Virginiana* and *J. Bermudiana*, lead pencil sheaths are made. Their berries are of some medicinal value.

The Yew, *Taxus baccata*, a large tree of Europe, is noted for the great durability of its wood, specimens having been found in the ruins of Nineveh. *Pinus Pinaster*, *P. Laricio* and *P. Maritima*, all of Europe, are used on the coast of Ireland and Normandy for fixing the sands. All are more or less ornamental. This is the case with *Pinus*, *Abies*, *Cedrus*, *Cupressus*, *Thuja*, *Taxus* and *Salsburia*. Of remarkable trees, there are the *Sequoia gigantea*, the giant Redwood; the Norfolk Island Pine, *Araucaria excelsa*, a specimen of which can be seen in the yard of the San Francisco postoffice, but which is not hardy here; and the Maiden Hair tree, *Salsburia adiantifolia*, the leaves of which are especially peculiar.

The Oak Family,

Cupuliferæ; numbers 330 species, of which 280 are members of the genus *Quercus*; is mostly confined to the northern hemisphere. For timber this order ranks next to the *Coniferae*,

Fig. I.

Live Oak—*Quercus virens*—reduced one-half.

the Oaks occupying a place second only to that filled by the Pines and Firs.

British oak *Quercus sessiliflora* and *Q. pedunculata*. These are extensively used for ship building in England; especially the first, whose wood is very tough, heavy and durable. The bark is much used in tanning and somewhat in

Fig. III.

Tan Bark Oak—*Quercus densiflora*—natural size.

the manufacture of dyes. It would be an experiment worthy of trial to import from England a quantity of acorns of the first species, as in all probability the tree might be

Very Profitably Grown Here.

Quercus virens, the Live Oak of the southeastern Atlantic States, (See Fig. 1), is very valuable also as ship timber. It should be introduced.

The White Oak, *Quercus alba*, is in the United States east of the Mountains, one of the most valuable of hardwood trees. Its timber when protected from the changes in moisture is very durable and that grown on particular soil exceedingly tough. (See Fig. 2).

Quercus Hindsii, a relative of the last is one of the most common of the deciduous oaks in central California. Its wood is not of great value being too brittle.

Quercus agrifolia is the common evergreen species and abounds in Oakland and vicinity. The wood is said to be rather brittle and not well adapted to use where toughness and strength are required. A form of this or pos-

sibly of another species is used somewhat for ship-building and it is said to give good satisfaction.

The Evergreen species in California are very variable, and much confusion still exists as to their specific limits.

The American Beech, *Fagus ferruginea*, is common east of the Mississippi valley. Its wood is heavy and dense and is much used for planes and other carpenters' tools. It is not found on this coast.

Castanea vesca, the Chestnut, furnishes a valuable lumber for cabinet work, it being light and nearly white. It is also used for inside finishing in houses. Its fruits are well known. The fruit of the European Chestnut is larger and better than that of the American variety. A species of this variety grows in California.

The Filbert, *Corylus avellana* grows in Europe. It is a shrub much like the Hazel of America to which it is very nearly related. Its fruits are the filberts of commerce. The Oak galls so largely used in inks and dyes, are produced on an oak (*Q. infectoria*) growing in Western Asia. These galls are produced by the punctures of a species of Cynips or gell-fly which makes these wounds in preparing a receptacle for its eggs.

Fig. II.

White Oak—*Quercus alba*—reduced one-half.

Tanbark Oak, *Quercus densiflora*, (See Fig. 3), is coming considerably into use and is found when properly prepared to be very tough and durable, and to be admirably adapted to use in the manufacture of agricultural implements.

Fig. IV.

Canyon Oak—*Quercus chrysolepis*—natural size.

The Cañon Oak, *Quercus chrysolepis*, is said by those who are familiar with the tree to be almost equal to the Live Oak of the East for ship-building, (Fig. 4). This species is found growing in the deep cañons of our mountains.

CAPTAIN RICHARDS shipped on the 30th inst., from Battle Mountain, five car loads of copper ore from the English company mine in Copper cañon, near Glendale. The ore from the mine is shipped direct from San Francisco to Liverpool.

WATER for mining purposes is getting very scarce, says the Nevada Transcript, and unless we get a "heap" more rain, times will be exceedingly dull. The miners are making the most of what water they have, but it will not last a great while longer.

THE yield of gold from placers and quartz in Montana, in 1874, is placed at \$2,360,170, divided as follows: Placers, \$1,864,170; quartz, \$496,170.

Two large new boilers have been received at the hoisting works of the Consolidated Virginia mining company, and will at once be set up.

Shall the Productions of the Soil be Patented?

The press—especially the agricultural portion of it—have given some space of late to the discussion of the merits of a bill now before Congress, which, in its design and provisions make the productions of the soil patentable. The bill provides that every resident of any State or Territory of the United States, who has been or shall be the originator of or discoverer of any new and valuable fruit or plant, being a new variety of any grain, vegetable, vine, herb, root, tree, wood, plant, shrub or flower, or the seeds, roots, scions, bulbs, burs, eyes or cuttings thereof, and which shall not have been sold or publicly offered for sale, shall have the sole right and liberty of growing, propagating and selling such plant for the term of seventeen years.

Those who are, or profess to be, especially concerned for the rights of the agriculturist and horticulturist, declare that they cannot see why a man who produces an improvement in these departments should not possess the same right in them that is granted to mechanics and others. But, putting in this claim, is, to say the least, hardly opportune at the present time, when farmers are making a special effort to restrict patents, if not to ignore them altogether. But we do not really believe that the classes for whose interests this bill is supposed to provide desire its passage. In the first place, they would not derive any direct benefit from such patents, for such improvements do not originate with these classes. It is to the enthusiasts in these matters, isolated individuals, retired but ardent worshippers at the shrines of agriculture and horticulture, that we trace the improvements in fruits, grains, flowers, etc. The amateurs who were dependent upon commerce and the trades and professions, or who were independent of all these callings, have produced most of our improved varieties of grain, fruits, flowers, etc.

The originator of the celebrated Goodrich potato, was Dr. Goodrich, physician to the N. Y. State Lunatic Asylum. The grounds of the asylum afforded a good field for his experimental operations, and he found recreation from his arduous professional labors in the efforts which resulted in this celebrated seedling, which has been as widely known as any potato that has ever been produced.

We could mention many cases of a similar character, but will merely refer the reader to the brief sketches of new varieties of grain, vegetables, fruits and flowers, which, in a large proportion of cases that inform us they were originated by some physician, clergyman, or retired merchant or capitalist.

So if there is any royalty to be paid for these improvements it will come out of the pockets of the farmers instead of going into them; and there is a probability that a monopoly will thus be built up, more onerous to the agriculturist classes than any now existing. The producer and the consumer will alike be taxed to sustain a new and powerful order of middlemen. It is safe to predict that it will be new in every respect; for if money is to be the incentive to experiments in this field of invention, we may expect to see the enthusiastic, unselfish men to whom we have hitherto been indebted, slacken their labors, and their places supplied by an entirely different class of men. They have not, as a general thing, sought pecuniary reward; as a class they have been remarkable for their modesty and disinterestedness. Still they have not, by any means, lived lives of self sacrifice. The man who is, through a long course of years, employing his leisure hours in perfecting some seedling, grain, fruit or flower, is no more an object of commiseration or reward than is the trout fisher on the bank of some favorite stream. In mechanical inventions and scientific research great sacrifices of time and money are generally made before anything substantial is gained; but nothing of the kind is required in securing such improvements as this bill would make patentable.

Even though justice and the interests of agriculture and horticulture required the proposed protection by patents, is it practicable? If a farmer buys at a high figure a potato or an ear of corn of some new and expensive variety, will he not dispose of the increase from these as he thinks proper? Can he dictate to the purchaser thereof whether he shall eat all the potatoes, or plant a portion of them, and the same with the corn? And the surplus scions and runners which we remove from off our trees and vines; shall we be allowed to give them to friends and neighbors? It will be rather hard if we are denied this privilege; but without this restriction a patent on fruit would be of little avail; for a very large portion of the increase of choice fruit is brought about in this way; and the same rule applies largely to plain agricultural products. These patents are, it seems, to be good for seventeen years; but we apprehend it would require a larger increase of office holders to manage this thing seventeen months, even, than the country would submit to.

We have as yet heard nothing said in connection with live stock; but the sacrifices are greater in producing a clearly defined, valuable breed of cattle and horses, sheep or fowls, than any of the products referred to above; while the benefits which the country receive from the former are quite as tangible and permanent, and common justice would grant the stock breeder a patent as readily as it would to the originator of a variety of grain or fruit. But in tracing out the proprietary rights of the cattle or poultry breeder, what a fearfully bewildering series of cases of mistaken identity present themselves to the imagination!

GOOD HEALTH.

Dangers of Pork Eating—Now the Trichina Kill.

We condense the following from the *Health Reformer*:

When taken into the stomach the trichina is invested by a capsule. The fibrous capsule is very soon dissolved away by the gastric juices, thus setting at liberty the partly matured worm, which grows very rapidly, attaining its full size in about two days, being then many times larger than when first taken into the stomach, when its length is only about one-twenty-fifth of an inch. In about a week each worm gives birth to about 1,000 young, according to Leuckart, which immediately begin to penetrate the mucous lining of the stomach and intestines. This gives rise to violent purging and vomiting, but to little effect for the relief of the patient, for the worms are already secure in the walls of the intestines. In a very short time they find their way into all the muscles of the body, when the most painful symptoms occur. The patient lingers along for a few days, perhaps weeks, in the most distressing suffering, finally dying from exhaustion, or from suffocation caused by the great number of parasites infesting the muscles of respiration and thus preventing their action.

In less than two weeks after eating an ounce of infected meat a person might have in his intestines hundreds of millions of these rapacious animals, whose ravages no remedy can stay. Imagine the agony which a person must suffer, while this numberless horde of microscopic serpents are boring through the wall of his alimentary canal. The rapidity with which the body becomes filled with these loathsome creatures is most astonishing. Professor Dalton found 208,000 to the cubic inch in the muscles of a boy who died on the twentieth day after being attacked with the disease. When a person has been once poisoned he can never become free from the parasite. Death is his most probable end; but some survive after many months of suffering worse than death. In these cases the worm becomes incased in a calcareous sheath, which process takes place in from one to two years. Here they may live for an indefinite period, probably as long as the patient. Virchow mentions a case in which they were found alive in a cancer removed from a woman twenty-four years after they were received into her system.

Its Prevalence in Swine.

The trichina is found in cats, rats, mice, and various other animals, as well as in the hog, and it is probable that they are introduced into the latter by eating the dead bodies of the first mentioned animal. It seems to be the general belief that the disease is of rare occurrence in hogs, and need excite no apprehension. Various facts disprove this supposition, however. It should be remembered that the flesh of an infected animal may be apparently healthy to an unassisted eye for the trichina are microscopic objects, often being no more than one-seventh-third of an inch in length and one nine hundred and sixtieth of an inch in diameter. Careful observations have been conducted by scientific men to ascertain the frequency of the disease by examination of the dead carcasses sent to market. A committee of the Chicago Academy of Sciences reported in the *Medical News and Library* of June, 1866, that in 1394 hogs examined in different packing houses and butcher shops of the city they found an average of one in fifty affected with trichina. A gentleman in Louisville reported, as the result of extensive observations, that he found an average of one trichinous hog in every ten examined.

Frequency of the Disease in Man.

Until recently there has been no conception of the frequency of this disease. It is now positively known that many cases of supposed typhoid fever are really the results of trichina poisoning. Professor Janeway, Demonstrator of Anatomy at Bellevue Hospital, asserts that observations in the dissecting room had convinced him that the disease was of great frequency, not being discovered until revealed by post-mortem examination, the patient being treated for some other supposed affection. He found three cases thus affected in the short space of one month; and it is probable that the majority go undetected.

Trichinosis may simulate numerous diseases. In the first stages it would readily be mistaken for diarrhea, dysentery, or peritonitis. The later stages as closely resemble rheumatism and typhoid fever. The patient often dies in coma, the cause of which would be likely to be attributed to almost any cause but the real one.

Many unmistakable cases of the disease have occurred within the last ten years since public attention has been called to it. A physician last winter attended eight cases of the disease in a single family in Malcolm, Iowa. Several members of the family died in a few weeks. The remainder of the family survived but only to continue suffering. None of them have regained their health.

In Helstadt, Prussia, one hundred and three persons were poisoned by eating sausage at a public dinner. A large number of them died in a short time, twenty within a month.

In Germany 360 persons were attacked with the disease at one time. Large numbers of them perished miserably. Those who survived were doomed to carry about in their flesh, dur-

ing the remainder of their miserable life, myriads of loathsome worms encased in calcareous envelopes which sometimes forms around them, preventing their irritating action on the human system, and thus rendering the life of the patient possible, sometimes for many years after the first attack.

WHOOPIING COUGH.—No known means will arrest the disease unless it be the means recommended and practiced by the celebrated Brown-Séquard, which consists in keeping the patient insensible with poisonous doses of belladonna for several days in succession. If the patient does not die it is barely possible that he may escape the disease upon recovery from the effects of the poison. The cause of the disease is a poison which pervades the system. Recovery takes place when it is all eliminated and not before. Nurse the patient well, avoid exposure to sudden changes of temperature, but keep the air of the sick room pure as possible by ventilation. Give nourishing food, and administer a warm bath every other day.

USEFUL INFORMATION.

A Few Hints to Foremen.

To manage a gang of men properly is a matter that requires a more thorough knowledge of human nature than falls to the lot of thousands of foremen. There are hundreds of foremen who imagine that a great deal of noise, bluster and profanity is necessary to secure the performance of the greatest amount of honest labor. This is a grievous error.

If any one will take notice of a gang of men whose foremen is sour, cross and surly, and whose mouth is always full of oaths on the slightest provocation, either fancied or real, it will be seen that the men care little for what they are doing. They always keep at least one eye on the "boss," and as soon as his "back it turned" they commence to "soldier" at once. If he leaves them for a while, they are not anxious to make a good showing on his return, for they are sure of a season of abuse, however faithful they may have been in his absence. There is nothing to encourage them to extra exertions, and all they care about is to get along as easily as possible until pay-day.

Honest, skillful workmen are not likely to stay with such a man any longer than they are obliged to, and such foremen can seldom keep other than a gang of reckless, third-rate workmen together. They are continually in trouble; but little work is done, and that in a slovenly manner. Usually this kind of men manage their work without any system or regularity. The men get in each other's way; they get each other's tools; they take hold of things at the wrong end; everything is hurry and confusion, and the foreman imagines that because he has made a great deal of noise and the men have exerted themselves tremendously he has accomplished wonders, while in reality he has done but little.

At times a dozen men are set to perform what might easily be done by half that number, at other times a half dozen men are expected to do what would require the united efforts of twice that number. These foremen do not know how much a man can or ought to do. They go to work on a job headlong, without exercising any forethought or judgment, and the latter is seldom possessed by the class of men in question. These men have a very high opinion of their ability, when the fact is they are a positive injury to any person who may be so unfortunate as to employ them.

If a foreman is of a kind disposition, possessed of a cool head and good judgment, with a friendly feeling existing between himself and the men under his charge, they need no urging in cases of emergency. A cool-headed man is usually possessed of good judgment, and knows how to place men so that they can work to good advantage. Every move counts, and work is rapidly performed without any seeming hurry, whereas the snarly, quick-tempered man will worry and fret both himself and every one around him and accomplish but little. Good nature is indispensable to the successful management of workmen, but it should be accompanied with sufficient firmness and decision to prevent any undue liberties on the part of the workmen.

In the machine shop, the foremen who has the last-mentioned qualifications will have everything shipshape. Every workman knows what would displease the "boss," and takes especial pains to have everything in good order. He does his work in the best manner, both for the praise he expects to receive from his foreman and the interest he feels in the welfare of his employers.

When a workman knows that faithful, honest labor is appreciated, he is not slow to take a lively interest in the work in hand, and it is of great importance that individuals or corporations employ no foremen who are continually at war with the men under their charge.—*R. R. Gazette*.

A FRENCH chemist claims to have discovered a means of extracting moisture directly from the air for the irrigation of land in dry seasons, thus rendering the agriculturist independent of rain or irrigation by canal. By the application of chloride of calcium to fields, meadows, roads, and sandhills, the land is made to absorb abundant moisture for three days.

Forging Tools.

A correspondent of the *Scientific American*, who has evidently had much experience in forging tools, writes to that paper as follows:

"My experience has been that no amount of skill and care in hardening and tempering can make a right down good tool of one not judiciously forged. In forging bring the steel to a mellow heat, and keep it so until you have your tool forged to shape. As the heat declines to black hot, compact your steel by light hammering on the face of the tool, but do not hammer the tool edgewise. Now if the tool is ready to harden, when it is heated it will swell so as to loosen up the compacting that was done by light hammering as it was cooling off. So it follows that whatever will harden the steel at the least heat will do it the best.

I use strong cold brine, and want it near the fire, so as to utilize all the heat in the tool. As soon as the tool is cool I dip it in oil (sperm or whale oil preferred). Now hold the tool over a well burnt-down fire, without the wind on. Hold the tool so as to retain as much of the oil on it as possible. Now tip it up slightly so as to make the oil flow from over the hottest part to the edge. The oil becomes a carrier of heat, and will help to let down the temper (exactly alike every time) from any thick part to a delicate cutting edge. I think the color that comes on the steel under hot oil can be depended upon much more with than without oil, although it (the color) will be a little tardy. In letting down the temper I want to do it slow enough at last, so that I can lay down the tool to cool off, and not have to dip again. But if it is going too low, I invert it, and dip the body part and leave the edge out. There are very few tools in which I like to leave heat enough in the body to let down the temper with, for this reason: as I grind back on the tool, the cutting edge is apt to get a little farther from the outside film of refined steel. This film is harder than the steel under it, so I would leave the tool slightly harder a little way back from the end; whereas, if you run out heat enough from the body of the tool you will very soon be at work with a tool altogether too soft.

Treatment of Tin Scraps.

In the manufacture of tinware it is said six per cent of the whole of the plates employed disappear in the form of scraps. This enormous waste in sardine boxes produced in Nantes, in 1869, nearly 400 tons of scraps; Birmingham produces some 20 tons per week, and Paris 50 to 60 tons per month. A small quantity of these scraps has always been used in various ways, such as the addition of small quantity to the pig iron intended for steam cylinders; another small portion was treated by concentrated sulphuric acid, or a solution of caustic potash, but no one treated tin scrap on a large scale until a short time since. The subject has been treated by M. Kneusel, in the *Bergund Uttamannische Zeitung*, and an abstract of his paper is given in *Iron*. The mode employed comprises four chief operations: 1.—Treatment of the scraps by means of boiling in water acidulated with hydrochloric and nitric acid, until all the tin is dissolved. 2.—Precipitation by means of zinc of the tin contained in the above solution and washing of the precipitate. 3.—Solution of the precipitated solution in hydrochloric acid and crystallization of the chloride of tin. 4.—Utilization of the iron scraps when despoiled of the tin.

STUPID NEWSPAPER REPORTS.—Ignorance about the most common operations of different trades does not appear to be confined only to many of our own newspaper editors and contributors, but Germany, and France lately gave a striking illustration of it in an absurd report which was going the rounds of the papers there, and finally found its way into a French paper published in New York. It stated that some mischievous Frenchman had painted the four large cast-iron lions, supporting the Waterloo monument in Brunswick, Germany, orange by means of red lead, and that they could not get the paint off, but had to paint them over again with black. We supposed that almost every one knew that it is very common to paint iron, especially when rusting is feared, first with red lead ground in oil, this being a protection almost as good as galvanizing, while at the same time it causes the subsequent black paint to adhere better and dry quicker. There was evidently no mischief in the operation, it being the regular method employed by the painter who had undertaken the job, and who understood his business perfectly well.

NEW WAY OF CUTTING VENEER.—S. C. Carpenter and Dr. M. E. Williams, of Green Bay, Wis., have constructed a novel and successful machine for cutting veneer. There is a machine for cutting veneering from round blocks, but it is quite different from this. In that, machine the knife is parallel with the log, and in some kinds of wood the beauty of the grain is lost, while with the knife set at an angle it is preserved, and this is the merit of the new machine, which has a conical-shaped cutter like a pencil sharpener, and commences cutting at the end of the log, the log feeding into the knife or the knife to the log on a lathe, the veneering coming off in the shape of a scroll. The machine cuts the veneering one twenty-fourth of an inch thick, and the log would therefore cut about 24,000 feet.

DOMESTIC ECONOMY.

Humbbug Food.

A careful observer will not accuse us of exaggeration when we say that thousands, yes, millions of people are daily attempting to supply the alimentary wants of their bodies with compounds which are the veriest humbugs extant. Very earnest and just protests are raised against the many lottery swindles and numerous other deceptive operations constantly being brought to light; but the majority of us daily allow ourselves to be "taken in" by the savory but innutritious and unwholesome mixtures which modern cooks furnish us. A multitude of shrewd farmers, merchants, lawyers, and even doctors, who pride themselves upon their tact and cleverness, are unwittingly cheated several times a day by their dear wives, although we should in justice say that the latter are in total ignorance of the perpetration of any offense. And yet, although a matter which is so intimately related to life and health as is food and drink is of vastly greater moment than mere material or pecuniary affairs a protest against these wholesale dietetic swindles is seldom heard.

The common terms, "rich" and "poor," as applied to food, are excellent illustrations of the ignorance of the popular mind respecting the real dietetic value of articles of food. Thus we hear, and sometimes ourselves speak, of rich pies, rich cakes, etc.; and we talk of poor food and low diet, including in the latter classes articles which are deficient in those elements which would give them rank in the class of "rich food" if present. In our estimation the terms rich and poor should be applied to articles of diet in exactly the reverse of their present application. If the word "rich" has any proper significance as relating to food, it should certainly be applied to such articles as contain the materials requisite for the maintenance of the body in the largest proportion, and in the most available condition. This would require us to denominate as "rich," such articles as Graham bread, oatmeal pudding, and similar delicacies, while the appellation of "poor" should be applied to pies polluted with lard and spices, cake made indigestible with soda, butter, and a profusion of sweets, and all articles of like character. So, too, would we be obliged to term "poor" the numerous "fried" dishes which figure so largely in the popular bills of fare. But poorest of all is the diet of the man who allows himself to believe that in taking a glass of "bouillon" he is taking a "long drink and a square meal at the same time," as the flaming placards in the saloons assert.—*Health Reformer*.

BROWN BREAD.—The sweetest bread ever made.—Take three pints of coarse yellow corn meal, scald it with three pints and a half of boiling water, add two pints of coarse rye meal after the corn has cooled. Knead thoroughly with the hands. Take it out into a stoneware crock which is a little larger at the top. The quantity here given will make a vessel which holds five or six quarts. Place it immediately in the oven, after smoothing over the top with a spoon frequently dipped in cold water. Cover with a stone or iron plate, and have but little heat in the oven. It should take three hours to begin to bake, then bake slowly four hours. Leave the loaf in until the oven cools off, if it is several hours longer. It should be dark-colored, light and firm, with a good soft crust. A round-bottomed iron kettle will do to bake in. Try it.

SPLIT PEA SOUP.—Put one pint of split peas, which have been previously soaked in cold water four hours, into two quarts of pure soft water. Let them boil for one hour, then add one carrot, one persnip, one turnip, two onions, a small head of celery and a little mint, all cut small, and boil another hour. Strain the soup from the vegetables, and thicken it with a little Indian meal, previously mixed in cold water; boil the whole for ten minutes more, and serve in a tureen with toasted or plain wheat meal bread. Mix the vegetables well, and put them into a mould or basin, and then into a vegetable dish, and serve with steamed or baked potatoes. Salt moderately.

APPLE BREAD.—Weigh one pound of fresh, juicy apples, peel, core, and stew them to a pulp, being careful to use a porcelain kettle or a stone jar, placed inside an ordinary saucepan of boiling water; otherwise the fruit will become discolored; mix the pulp with two pounds of the best flour; put in the same quantity of yeast you would use for common bread, and as much water as will make it a fine, smooth dough; put into an iron pan and place in a warm place to rise, and let it remain for twelve hours at least. Form it into long-shaped loaves, and bake in a quick oven.

BAKED CUSTARDS.—One pint of cream, four eggs; cinnamon; almond-flavor, and three ounces of sugar. Boil the cream with a piece of cinnamon; pour it into a basin, and when cold add the eggs, well beaten and strained, the sugar powdered, and a few drops of almond-flavor. Bake in small cups, in a cool oven.

STRING BEANS should be string, broken in pieces, and boiled an hour or two, and seasoned the same as shelled beans.

ments; Meetings and Dividends; Review of the Stock
Market for the Week, 168.

MINING SUMMARY.—From the various counties
in California and Nevada, 168-9.

MISCELLANEOUS.—Disposing of Sewer Gas; A
Wire Tramway for Mt. Diablo; Pacific Coa at Woods;
Shall the Productions of the Soil be Patented, 169.

Straw Burning Engines.

Messrs. Treadwell & Co. have recently re-
ceived a Hoadley threshing engine, with a
number of new improvements, suggested by
the necessities of field work in this State.
Among the improvements are the cut-off gov-
ernor, which consists of an arrangement of
mechanism so attached to the shaft as to move
the eccentric to a different angle with the crank
by a change of speed, the centrifugal motion
overcoming the tension of a pair of springs,
and these springs in turn acting to give the
centrifugal force. The fire grate consists of
hollow tubes, which are coupled with another
set of vertical tubes, standing in front of the
flues, and these tubes are connected with the
water space, so that the fire is bounded on two
sides by this "grillage," as it is called, and
enough more steam is made to supply all the
waste of the steam boiler.

This engine has been adapted to burn straw,
and a partial test of the invention was made in
front of Messrs. Treadwell & Co's on Saturday
last.

The most satisfactory tests were, however,
made before the engine was sent from Hoad-
ley's works, and consisted of two trials of four
or five hours each, with an ascertained load.
During these tests the engine, which is rated at
15-horse power, showed a maximum of 24-
horse power and a total average of 18-horse
power. Indicator cards were taken from time
to time which were more than usually fine.
Steam was got up by simply igniting the
straw with a match, and no difficulty was ex-
perienced in keeping steam up to a high pres-
sure during the entire run. These already
popular engines will be rendered more effective
than ever for the coming season's work.

LECTURES ON GEOLOGY.—J. W. Taylor, of
Utica, N. Y. (formerly Curator of the State
Cabinet of Natural History and Geology at
Albany), is to give a course of four lectures at
the hall of the Academy of Sciences, in this
city. We are not able at present to state the
time of the delivery of these lectures, further
than that they take place within a few days.
Mr. Taylor has a good reputation as a geologist
and lecturer.

The St. John quicksilver mine, Solano
county, yielded 225 flasks of quicksilver dur-
ing the month of February. The force of
workmen has lately been increased, and the
product will soon be doubled.

New mineral discoveries are reported in Bear
valley, San Bernardino county, and prospe-
ctors are flocking to that locality.

Among the Foundries and Machine
Shops.

Business at the machine shops of our city
continues unusually brisk. Contracts for new
work are constantly being made, and most of
the foundries are taxed to their utmost capacity
to fill their orders.

Risdon Iron and Locomotive Works.

At this establishment is in process of con-
struction a piece of mechanical skill which is
unusually interesting. We refer to the eleva-
tors, five in number, to be used in the Palace
Hotel. The elevators are strongly constructed
and capable of lifting one hundred persons
from the ground floor to the upper seventh
story in thirty seconds. These elevators are
worked by hydraulic pressure.

The power is obtained by two sets of en-
gines, 9½-inch cylinders, acting on two sets of
pumps, three to a set—which are arranged to
work either together or separately. These
pumps are four inches in diameter and two feet
stroke. They pump from a tank into an accum-
ulator, 22 inches in diameter and 20 feet long,
the rem of which is loaded with a weight-box
containing about 100 tons of sand. This ram
is connected with the throttle-valve of the en-
gines, so that when the box or ram is at its
greatest height the steam will be shut off and
the engines stopped. The power is distributed
from the accumulator through 4-inch pipes
to each hoist, and immediately upon the use
of the water by the hoist or other machinery,
the ram descends and gives off its stored power.
The engines then commence to pump and re-
place the water taken out. All the water used
is again sent back to the pump-tank and thus
the leakage and evaporation represent all the
water wasted. This wastage is so slight that a
very few gallons per day will be sufficient to
supply the loss. The whole machinery is so
arranged that an accumulated power of 175
horse-power is constantly stored up and may
be put in operation in a few seconds.

One peculiarity of this power is that it can
be distributed by means of pipes to almost any
reasonable distance. It is comparatively new
in this country but in England, where it was
first inaugurated, six and eight miles of main
pipes, with numerous connections, have been
laid. There are three steel ropes attached to
each elevator either one of which is capable of
sustaining it alone if necessary. The plunger
of the accumulator is a rolled shaft of iron
weighing some twenty tons. The amount of
water in use will be about 1,000 gallons, but as
this is used over and over again there really is
not more than a few gallons expended in a day.
When we state that this system of power is ca-
pable of being used in mining operations some
idea may be had of the great value its applica-
tion may be to our State.

The application of this power in the Palace
Hotel is being carried on under the direction of
Mr. Joseph Moore and Mr. George W. Dickie,
of the Risdon Iron Works.

Miner's Foundry.

This establishment is crowded with work.
Among other things a locomotive is being con-
structed for the Walla Walla mill to be used in
hauling logs and timber. A narrow-gauge
railroad has been built into the redwood forest
seven miles from the mill, and this engine will
be placed on it. A great deal of timber has
been lost in the Columbia river in times of
freshet by the breaking of booms and the con-
sequent escape of the logs to the sea. It is be-
lieved that the construction of railroads for the
transportation of logs will in many cases prove
economical and certainly much more conveni-
ent.

Golden State Foundry.

A number of new contracts have lately been
made by the proprietors of this foundry.
They are about completing a lot of grading
cars for the Los Angeles and Independence
railroad. Saw mill work for a mill in Sonora,
Mexico, is being constructed. Battery work,
shafting and other mining machinery is in dif-
ferent stages of finish for the following mines:
Bunker Hill Quartz mine, Reddington Quick-
silver Co., Benton mine, Indian Queen mine,
Socrates Quicksilver mine and the Justice
mine.

Occidental.

At this foundry a large amount of miscella-
neous work is being done. The whole force is
employed and new work coming in every day.

From the Wheatland Free Press we learn
that a party of miners backed by San Francisco
capitalists, are actively engaged in prospecting
for iron in the neighborhood of the Suspension
bridge. They have discovered detached bould-
ers bearing eighty-seven per cent of iron, and
are sanguine of success in finding the lead to
which they belong.

THERE is between thirty and forty inches of
water running out of the Suto tunnel at pres-
ent. The Superintendent anticipates striking
a ledge within a short time.

The Gila mining company have purchased
the Reveille mill and mine in that district, and
will have the former at work on the 10th in-
stant.

A CLEAN UP of 97 tons of rock from the Crater
mine, Placer county, last week, yielded 250
ounces of gold.

Hydraulic Mining at Gold Run—The Blue
Lead Ancient River Channels.

Mr. W. A. Skidmers, of this city, has recently
made a visit to the hydraulic mines, at Gold
Run, Placer county, where some extensive
operations are being carried on. From him
we have obtained some interesting information
concerning the hydraulic mines on the Blue
Lead, which is embodied in the following:

The Mining districts of Gold Run and Dutch
Flat comprise nearly 2,000 acres of auriferous
gravel, situated on the line of the ancient river
popularly known as the Blue Lead. The
Central Pacific railroad crosses this channel
diagonally and forms the dividing line between
the two districts. From the window of the
cars the passing traveler looks with surprise
and wonder on the immense excavations on
either side, produced by the hydraulic opera-
tions of sixteen years; but fails to realize the
fact that the ground embraced within the
scops of his vision—about eight hundred acres
in extent—has contributed no less than ten
millions of dollars to the gold product of our
State, and that the most reasonable estimates
of the contents of the ground still in place,
based on the actual yield of the lower strata
now being mined, would not place the aurifer-
ous contents of these districts at less than one
hundred millions of dollars, requiring from
thirty to forty years for their exhaustion.
Neither can he conceive the vast enterprises
now in progress to open the bottom of these
districts by means of bed-rock tunnels run
with all the appliances of modern mechanical
skill and engineering.

Many theories have been advanced, with a
greater or less degree of plausibility to account
for the origin of these vast

Deposits of Gold Bearing Delritus.

Only on one point is there a general agree-
ment—that they were deposited by the action
of water. Each of the various theories ad-
vanced are reasonable when applied to the par-
ticular locality which the writer describes, but
they do not admit of universal application. In
some cases there are undoubted evidences of
channel action, indicating the existence at
some remote geological era of a system of water
courses whose line of drainage was nearly two
thousand feet higher than that of the present
time. What, then, must have been the average
surface level? Certainly much higher than at
the present time. The grade of the ancient
river system was much greater than that of our
day. Carefully prepared data founded on sur-
veys shows it to have been from six to eight
feet to the mile. This is greater than that of
the swiftest rivers of Europe, as their grade is
rarely more than four or five feet to the
mile. It is also evident that a much larger
volume of water than that of the modern
watershed flowed in these ancient rivers. Huge
masses of rock were carried for great distances
and deposited finally at a point remote from
their first resting places. Ledges of quartz
were broken and disintegrated, thereby releas-
ing their gold and concentrating it in the beds
of the ancient streams, where it was destined
to remain for centuries, until again released—
this time by the artificial appliances of hydrau-
lic mining. Trees of great size and not differ-
ing greatly from the present species were torn
up by their roots and carried along the fierce
torrent, until meeting with some obstacle, they
lodged, and in the course of time became car-
bonized, or in some instances petrified.

Everything points to the supposition that
these events occurred after some great climatic
change, and it is not unreasonable to suppose
that it was after the glacial period. The line
of drainage was not materially different in
direction to that of the present time, namely—
from north to south—but the ancient channels
have been in most instances cut and broken
by the feeders of the modern streams, which
rising high in the Sierra pursue a direction
from east to west until they reach the principal
watercourses—in our time the Sacramento and
the San Joaquin rivers. But the

Ancient Channel System.

Which is closely and unmistakably marked on
the line of the Blue Lead from the volcanic
ranges of Plumas and Sierra counties to the
low hills on the borders of the great valleys.
was not the only line of drainage. In the
counties of Trinity and Klamath we find a sys-
tem of drifts extending for miles, which had
its ancient debouchure on the Pacific ocean.
This drift, which may be traced for over forty
miles, was of great depth, and seemed to have
filled pre-existing valleys, which are now occu-
pied by high ridges of auriferous gravel. This
system may possibly be traced to Oregon and
connected with the gravel beds on the high
mountains mentioned in a late number of the
Press by a correspondent, who erroneously
supposed he was at the head of the Blue Lead
system. The Blue Lead system of drainage
had its source of supply in Lassen and Plumas
counties, where its sources are covered with
mountains of superincumbent lava, whose flow
caused the change or modification of the drain-
age system of the plicene era. These streams,

like all modern rivers had numerous affluents,
and the points of convergence are plainly indi-
cated, as at Dutch Flat, Placer county, and
Forest City, Sierra county.

An impression is common, particularly
among Eastern and English travelers who visit
our mines, that the sections of the

Ancient River Beds

Situated in detached masses and patches, so high
above the present water courses, are the results
of volcanic upheaval. This is clearly errone-
ous, as it is manifest there has been no change
of the plans of level of the old streams—as
they may be followed continuously on the same
grade for miles, except where interrupted and
broken off by the modern water courses, and
even here their continuation can be easily
traced across the streams. There seems to have
been no great eruptive disturbance since this
period which filled the ancient rivers. The
difficulty is in connecting the various chan-
nels consistent with a system of drainages,
and this would exist with respect to our
modern streams if they were submerged by
masses of lava. Thus, if we look at a map
of the State, and imagine this state of things,
we can see that the Sacramento and San
Joaquin rivers would appear as one and the
same stream.

The so-called

Blue Lead

Is an ancient river bed filled with gold-bearing
gravel in alternate strata varying in color,
thickness and hardness. The material is
principally composed of pebbles and boulders
of quartz, slate and greenstone, reduced by the
action of attrition to rounded or oval shapes,
and frequently strongly cemented by iron and
silica held in solution in the waters of the an-
cient streams, alternated with strata of pipe
clay and sand which are generally non-pro-
ductive. The gold occurs in minute particles
throughout the superincumbent dirt and gravel,
and in coarse particles in the lower or blue lead
stratum, while on the slate bed-rock it is some-
times found in nuggets, weighing from a few
grains to an ounce or more—the latter being of
rare occurrence. Where the bed-rock was
soft the gold has penetrated it to the depth of a
few inches, and this matter is taken out and
reduced in the stamp mills. The finer gold,
or that portion of it which is visible to the
naked eye, is usually in flat or "scale" form;
the coarser pieces are always water washed and
rounded, presenting an angular surface. These
latter are occasionally found in "nests" or ag-
gregations, lying behind some boulder which
formed an obstruction in the channel, at the
termination of an eddy, or in a crevice of bed-
rock. This mode of occurrence is not un-
common in Gold Run and Dutch Flat districts
where the bed-rock has been exposed. The
surface dirt is always the least productive and
the bottom stratum the richest. The various
layers between these constitute the averages
"hydraulic dirt" of the district, as the lower
stratum being strongly cemented is run
through stamp mills, and the gold saved by
amalgamation in battery and the use of sluice
boxes. The system of hydraulic mining is so
fully described in the able articles of Mr.
Waldever, now being published in your col-
umns, that it will not be necessary to allude to it
here.

The Infinite Divisibility of the Gold

Existing in these accumulations of detritus can
only be appreciated by comparison with some
familiar standard of size, weight and value. If
we take our smallest gold coin—the gold dollar
—weighing 25.8 grains, and cut it into two
hundred parts of equal size, we should have
two hundred specks or "colores," each weigh-
ing thirteen one hundredths of a grain, of
the value of one-half a cent each. Now let us
imagine thirty of these colors diffused through
a cubic yard of gravel or dirt—that is to say
through 120 miner's pans, for a pan contains
about 400 cubic inches, and 120 pans may be
estimated as a cubic yard for purposes of com-
parison. It will be seen that if we obtain one
color to four pans (assuming that we obtained
all the colors), this would amount to but fifteen
cents to the cubic yard—a ratio much higher
than the known product of hydraulic mining in
these districts for the past sixteen years of their
history and development. And yet so little is
known on this subject by interested parties,
that at a meeting of the London stockholders
of a prominent claim in Gold Run District,
when the statement was made that a prospect
had been obtained of the lower or Blue Lead
stratum of the company's ground, which showed
two dollars a pan, (a statement which the writer
has verified), one of the directors gravely in-
formed the stockholders that even two dollars
per cubic yard was considered good hydraulic
dirt.

In Gold Run District

The depth of auriferous gravel from grass roots
to bed rock was originally from 240 to 300 feet,
and of this scarcely more than 100 feet has
been removed. The width of the pay between
rim and rim is about 1,000 feet. This dead
river, as it may be appropriately called, is at
this point 1,350 feet higher than the North
Fork of the American, which has broken
through it, leaving a section of the ancient
channel exposed on the lower end of Gold Run
District, where it is opened by the tunnel of
the Indiana Hill Cement Company. The river
at this point had a gradual north by east
course, and may be traced northward for many
miles, being cut by the eroding influence of the
modern streams. The grade was about six
feet to the mile.

During the first five years of hydraulic mining

In Gold Run District (1865 to 1870), the average yield per cubic yard was not more than five cents. This average would probably be increased to ten cents if it should take the product for ten years (1865 to 1875), as the ratio of gold increases with each successive bench removed. What it will be five years from now it would be hazardous to conjecture, in view of the recent determination of the rich character of the bottom of this channel as developed by the workings of the Indiana Hill Cement mining company and the prospect shaft of the Gold Run Hydraulic mining company of London.

In the neighboring district of Dutch Flat, the average yield of the upper strata has been somewhat greater. An estimate of the cubical contents of the upper stratum of a tract of twenty acres washed to a depth of seventy feet, showed a yield of six and three-quarter cents per cubic yard. In this case accurate accounts were kept of the gold product. The average yield is increased from year to year as the lower and richer strata are run off. And yet, with the seemingly slight yield noted above, hydraulic mining has been a remunerative business in these two districts.

At the extreme south end of Gold Run district is situated the ground of the

Indiana Hill

Cement Mill and Mining Co. Standing on the bed-rock at the mouth of their tunnel and looking southward across the great canon of the North Fork of the American river which has here eroded a gorge two miles in width and half a mile in depth, we can discern the continuation of the Blue Lead, on the same level, on the mountains forming the north slope of the North Fork, where it is extensively worked at Iowa Hill. The breakage of the channel at this point enabled the Cement company to attack their ground parallel to the drainage line, instead of by means of a rim rock tunnel run at right angles. A tunnel has been run "up stream," and breasts of 150 feet in width are being opened toward the west rim. This system here pursued is known as

Drift Mining.

The cement constituting the bottom stratum is taken out to a height of four feet from bed rock and run through an eight-stamp battery. From 50 to 80 car loads of the dimensions of twenty cubic feet are run through every twenty-four hours, the amount depending on the character of the dirt, which varies in hardness from month to month. The record of this company for the past three years, dating from the purchase of their ground has been unprecedented in the annals of this class of mining, and has demonstrated the immense richness of the bottom of this portion of the Blue Lead. The records of the company show an average yield of \$5.76 per cubic yard. This is exclusive of an occasional rich prospect which does not enter on the mill returns. During a recent visit of Mr. Skidmore to the this ground, a washing of one bucket of dirt yielded \$126 worth of gold. Last November about \$1,000 was taken from three car loads, and "pans" containing from \$20 to \$50 are occasionally washed. The owners are not capitalists but hard working practical miners.

Immediately north of and adjacent to this mill company's property we find the extensive operations of the

Gold Run Ditch and Mining.

Locally known as the Miner's ditch company (of Gold Run), and of the Gold Run Hydraulic company (limited) of London. This first named company, under the superintendence of Mr. Jas. Gould, are running an immense bed-rock tunnel through the east rim of the channel, for the purpose of reaching their claims, and eventually of serving as an outlet to the whole district. The starting point selected was on Cañon creek, a deep ravine emptying into the North Fork. The objective point is an old prospecting shaft, situated near the center of the district, known as the "49-50" shaft. The main tunnel is 8x8 feet in dimensions, and will be 2,000 feet in length. Eight hundred feet of this had been completed on February 15th, and two branches had been run to open ground in the vicinity, pending the completion of the main adit. One of these branches, nearly as large as the main tunnel in dimension, had been run 1,300 feet, and the "raise" commenced. The company expect to be ready to wash in June, 1875. This successful introduction of the Burleigh drill in California render these long tunnels no longer the formidable obstacles they were once considered.

Another Tunnel.

The Gold Run Hydraulic mining company (limited) tunnel will, when completed, be 840 feet long, eight feet wide, and eight feet high. 450 feet of this tunnel has been completed and the Miner's ditch company is driving it ahead at the rate of 130 to 140 feet per month. The tunnel at this shaft will be at least 60 feet in the bed-rock, being ample grade to work out the whole property. There has been a shaft sunk to bed-rock, 181 feet, through rich gravel the entire distance, and at the bottom of the shaft they struck soft, shelly bed-rock, which was actually yellow with coarse "lead" gold. This tunnel, when completed, will enable them to successfully work this vast deposit of auriferous gravel to bed-rock. They expect to have the tunnel completed by the middle of June next, and the incline raised and ready for washing at the commencement of next water season. They will put a five-foot flume in the tunnel, and several undercurrents. This "rig" will be first-class in every respect, and cannot fail, when properly opened to bed-rock, to yield

large profits to the fortunate owners in England.

The last named tunnel is also a branch of the main adit of the Miner's ditch company, work is proceeding rapidly—142 feet having been made in February. The Gold Run hydraulic company of London is in charge of Mr. J. A. Stone as manager or superintendent. In the selection of mining superintendents for their hydraulic operations in California, our English consuls have exercised remarkable judgment, and in no instance have had occasion to regret their choice. All their local managers, like Mr. Stone, are practical miners, familiar with this branch of mining and generally old residents of the district in which their property is situated. Some of our Eastern quartz companies might profit by this example, instead of sending dry goods clerks to take charge of quartz mines.

To the traveler there are no points of greater

Orchard Oriole.

The orchard oriole enters the Southern States from South America early in March, and continues there until October. In the more northern regions, it of course arrives later and departs earlier; but it does not often go further north than Connecticut. The migration from south to north is performed by day, and singly, the males preceding the females by a week or ten days, frequently alighting on the top of trees, to rest or feed. They exhibit a great repetition of motions of the wings, although gliding through the air for a few yards only at a time, and, while about to alight, as well as afterwards, perform strong and well marked jettings of the tail.

As soon as they reach the portion of the country in which they intend to remain during the time of rearing their young, and where

THE ORCHARD ORIOLE.

interest than Gold Run and Dutch Flat Districts. Here may be seen hydraulic mining on a scale of magnitude not attained elsewhere in the States and here may be studied under peculiarly favorable circumstances the channel system of the phocene age as illustrated by the great Blue Lead.

There are many other features of interest in this and adjoining districts of Dutch Flat, such as the Moody & Kinder tailing claim and the Cedar creek claims (of London), this latter near Dutch Flat, which will amply repay a visit to the traveler who wishes to study our hydraulic mining system.

QUARTZ SPECIMENS.—If any of our mining friends have any good specimens of gold quartz suitable for cutting, to make jewelry, etc., by addressing us we can inform them where they can get from \$18 to \$20 per ounce for the gold. Miners owning mines from which quartz of this class is procured can sell the good specimens to more advantage than they can crush them. There is a demand here for good quartz specimens of a character to be cut for jewelry, so our mining friends can save that they have and easily dispose of them at good prices. The more of them the better.

THE mines in Little Cottonwood, Utah, are jammed with ore awaiting transportation to the smelters.

they are always welcomed with pleasure, these birds exhibit all the liveliness and vivacity belonging to their nature. A little time is consumed before the female is won by her frisky wooer, the singing and gyrations of which are then very ardent; and, as soon as they have paired off, the most active industry is evinced. They resort to the meadows or search along the fences for the finest, longest and toughest grasses they can find; and, having previously fixed upon a spot, either on an apple-tree or amid the drooping branches of a weeping-willow, but which is very apt to be near the habitation of man, they begin by attaching the grass firmly and neatly to the twigs immediately around the chosen place. The filaments are twisted, passed over and under, and interwoven in such a manner as almost to defy the eye of man to follow their windings. All this is done by the bill of the bird. The nest is hemispherical, and supported by the margin only, finished outside and in with long slender grass, some of which goes around the nest several times, as if closely woven. But softer and warmer materials are used in the more northern ranges of these birds.

Figs, mulberries, strawberries, and various kinds of fruits are eaten by these birds, but not to a very injurious extent, their chief reliance being upon the pernicious insects of the garden and field.

Important Mining Suit Decision.

A decision has just been rendered in the great quicksilver mining case of Stone vs. the Geyser Quicksilver Mining Co., which has been on trial since February 26th at Santa Rosa. This case has created a great deal of interest, not only here but throughout the entire State, involving property valued at millions. The question at issue was, whether the original locators should get possession of the mines or the late holders, who claim that the original owners had abandoned their claim to the property.

A statement of the case may be briefly summarized as follows: In the early part of 1860, 20 claims were located in the vicinity of Geyser Springs. The first recorded was the Pennsylvania company, which included twenty claims as they were called, of 150 feet each, and the others in the following order: Healdsburg, 17 claims; Empire, 30 claims; Russian river, 14 claims; Gibraltar, 10 claims; Chaparral, 15 claims; Petaluma, 11 claims; Buckeye, 12 claims; Boston, 2 1/2 claims; Alta California, 15 claims. These claims, 127 in number, were consolidated and incorporated under the title of the Geyser Quicksilver mining company. Some prospecting was done. In July, 1871, the Last Chance, New York and other claims, were consolidated with the prior consolidation, and the company took the name of the American Quicksilver mining company. Some further prospecting was done. Finally, on the 28th day of April, 1873, the ground was sold, with the assets of the company, on attachment for \$496.50 and costs of suit, for goods, wares, etc., sold to the company by Ellis Brothers, and was purchased by F. G. Hahman at Sheriff's sale. After this, the affairs of the Geyser American quicksilver mining company faded from sight and memory.

On the 25th of November, 1871, W. H. Hopkins located the old Kentuck mine, part of which is claimed as the old American ground. The old Pennsylvania had, prior to that, been located as the Geyser, and shortly afterward the old Petaluma was located as the Missouri mine, which lies just west of the old Foss tract on the Hog's Back. A law was passed by Congress taking effect May 10th, 1872, extending the time for work to be done on old claims.

S. A. Stone, the plaintiff in this suit, purchased the title which Hahman had acquired under the Sheriff's sale in 1873, and commenced suit for the ground. The defendants had, prior to that sale, relocated the mines, and claim to have expended a large amount of money in developing them, said to amount in the aggregate to over \$50,000. They claim that they were in possession of this ground before the passage of the Act extending time to work on old locations, that the claim of the American company had been abandoned, and that they are the beneficiaries under the Act, the plaintiff having done nothing to keep possession after the Sheriff's sale of 1873. Plaintiffs aver that they had not abandoned their claim, and the law of 1872 extended the time for them to work upon it.

This suit has been decided in favor of the defendants—a decision which has been received with rejoicing in Santa Rosa, Calistoga and elsewhere in that vicinity. The jury was only out about ten minutes. This suit is considered a test case of the rights of locators under the mining law of 1872, as against those who years ago abandoned their claims and now endeavor to set up claims to them.

The finest coal yet discovered on the Pacific coast, without any exception, is declared by some experts to be that lately discovered in Pierce county, Oregon, in the foothills of the Cascade mountains, near the headwaters of the Tacoma River, and from 25 to 28 miles from the town of Tacoma. The deposit there is known to extend over a region at least two miles wide and three miles long, and the seams are from four to eight inches in thickness.

In Alameda county, some twenty-four miles south of Oakland, there are 400 acres of land devoted to salt making. In winter the sea water is let in, and in June it is gone into the clouds, leaving the salt behind. The annual yield is 7,500 tons, and the table salt there made brings \$10 per ton, while the cost of making it is \$6 a ton. Forty men are employed in the business on these 400 acres.

J. T. ANDERSON, who has the old Felter place on Oregon Gulch, Trinity, recently sluiced into an old Indian burying ground and examined a number of relics which had been buried therein. Among others was a stone pestle of neat workmanship, and twenty inches in length. The Chinamen quit work immediately when the bones were found.

NOTWITHSTANDING the effort made to stop the flow of water in the Sutro tunnel, a small stream is still running. In order to allow the men to continue the work, the track has been raised and a ditch cut below it. Men are now engaged at the header, and hopes are entertained that the water will soon cease to flow.

The Phoenix mine, in Pops valley, Napa county, with only twenty-five men employed, is turning out ninety flasks of quicksilver per month.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and, recently introduced for general family use in San Francisco and neighborhood, is already in great demand. It is now the intention of the manufacturers to introduce it all over the Pacific Coast, at prices which will bring it within the reach of every household.

It is unequalled for cleansing Woolen Fabrics, Outlets, Carpets or Crockery; for Scrubbing Floors, Washing Paint, Removing Grease Spots, Shampooing or Hatting.

It renders water soft, and imparts a delightful sense of coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-spoonfuls to a wash tub of water. For bathing, use one table-spoonful in the bath tub. For removing grease spots, apply with a brush, undiluted, and wash with water afterward. For stimulating the growth of plants, use a few drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per quart Quart Bottle, 40 cents; per Half Gallon, 75 cents.

Also, SULPHATE OF AMMONIA for chemical purposes, fertilizing and the preparation of artificial manures. AMMONIACAL PREPARATION for the prevention and removal of boiler scale. CRUDE AMMONIA, for general manufacturing, and PURE LIQUOR and AQUA AMMONIA for chemical and pharmaceutical purposes.

Quartz Mill for Sale

At Mineral Hill, Elko County, Nevada, four miles from Mineral Hill Station, on the Palisade and Eureka Railroad, and 35 miles from the Central Pacific Railroad.

The Mineral Hill Silver Mines Company (Limited) offer for sale their new 20-stamp mill (dry crushing) built by H. J. Booth & Co. of San Francisco.

The mill is complete in every respect, with engine, Boilers, Stetefeldt Furnace and all modern appliances, and is as good as new, having only run two months upon ore.

The whole is offered very cheap for cash. For further information apply to

H. H. OAKES, Superintendent.

TO COPPER SMELTERS, BLUE-STONE
and Sulphuric Acid Manufacturers.

For sale or to lease, the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallo copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations realized \$30,000 for Bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 30 tons per day, which may be extended indefinitely. Cost of extraction, \$1. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. of pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Louis Chalmers, Silver Mountain, Alpine county, Cal.

WANTED—By a graduate of the Massachusetts Institute of Technology, who has had practical experience, the situation of Chemist or Assayer, or a position as Assistant in a Mine or Smelting Works. References given if required. Address, Q. E. STAFFORD, Toledo, Ohio.

7v25-tf JOHN TAYLOR & CO

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidity pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam direct into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller for the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. It is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and sets for themselves, at this office, 229 Fremont Street, San Francisco.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

THE AMERICAN TURBINE WATER WHEEL

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{2}$ 50.08; $\frac{3}{4}$ 69.64; $\frac{5}{8}$ 78.73
 $\frac{1}{4}$ 82.53; $\frac{3}{8}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

TEATS' PATENT FURNACE.

For Roasting, Desulphurizing, Chloridizing, and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air, stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the rollers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 16, October 31, 1874. For particulars address

D. B. MILLER & CO.,

No. 12 West Eighth Street, Cincinnati, Ohio

Circulars, &c., will be furnished, if required.

Home Industries.

The California Chemical Paint Company.

The stranger visiting San Francisco is attracted by the light and fresh appearance of its private residences. Instead of the heavy, sombre buildings of the Eastern States, the mildness and equable character of our climate allows the construction of much less substantial and, at the same time, more graceful edifices. What adds largely to the beauty of our private houses is the free use of the paint brush. Of course where paint is such an important article as it is in San Francisco, or for that matter, throughout the State, it is well for our people to become acquainted with the best and most durable manufactures. Prominent among our industries is the

California Chemical Paint Company, having their manufactory at the corner of Fourth and Townsend streets. This company are the sole agents on the Pacific coast for the Averill Chemical Paint, which has acquired such an excellent reputation in the East. The inventor of this paint, Mr. D. R. Averill, of Cleveland, Ohio, spent some twenty years in experimenting before he achieved success in producing a paint which has the characteristics most desirable—durability, elasticity, ease of application and beauty of finish.

These Points of Excellence

Mr. Averill claimed to have achieved it when he applied for his patent eight years since. From that time to this nothing has been neglected which science or capital could furnish to improve upon Mr. Averill's original invention.

The California Chemical Paint Company are manufacturing under the Averill patent but are constantly endeavoring to improve upon the patent article. The company was organized in this city in 1869, but has only been under the present able management since last spring.

The Officers Are:

President, Tyler Beach; Secretary, M. C. Jewell. At the manufactory on Townsend St., the process of grinding, mixing and packing is carried on. Here may be seen samples of the different shades of paint on hand, and if not just what is wanted, the chemist in charge of the compounding will mix the very tint required.

It is prepared at the manufactory and put up in quantities of a gallon and upwards ready for use. When wanted a quantity can be drawn off—no mixing is required—and if not all used returned to the package. One merit of the Chemical Paint is, any one can use it. The farmer if he wishes to paint his house or his barn has only to buy a brush and a package of this paint and apply it. He

Becomes a Painter.

For the time being. The value of this paint, aside from its permanency of liquid, consists in affording a means of protection to wood against the action of the elements, and also, as has been proved by experience, forming a coating comparatively

Fire Proof.

The company is also manufacturing a copper paint, which is nearly equal to copper itself for preserving the bottom of vessels from the action of the water and parasites of the sea. An iron paint for coating iron vessels is likewise in great demand. A visit to the manufactory of the California Chemical Paint Co. will well repay any one, and prove that what we have said is not, to use, perhaps, an appropriate expression, too "highly colored."

LAND PLASTER.—We are pleased to state that Messrs. Lucas, Gesner & Co. have established a mill at 215 and 217 Main street, in this city, for the purpose of manufacturing plaster of Paris for fertilizing and other purposes. The fertilizing influences of this material have long been known and appreciated in the Atlantic and Mississippi Valley States; but it has never been utilized in California, chiefly on account of the exorbitant price charged for it here—\$20. per ton. The above named firm is now enabled to supply a very superior article for \$10. per ton, and we understand that some farmers are already beginning to supply themselves, either with large quantities for general use, or with smaller ones for experimental purposes. There is no doubt that this fertilizer, if generally introduced, would prove much more efficient in the dry climate of California than it ever has done in the more moist regions east of the Rocky mountains. We shall soon refer to this matter more at length, and in the meantime would urge upon our farmers the propriety of at least experimenting with the material on a small scale this season, and thus so assure themselves of its value that they may apply it more largely another season, should the success of this year's experiment warrant them in so doing.

MANY of the miners holding claims on Prospect mountain, near Enreka, are hard at work on their mines, and good ore has been found in several instances. The mountain is dotted with groups of miners searching for the hidden treasures. The greatest activity prevails among them, and when the snow will have disappeared Prospect mountain will be heard from.

THE total yield of the Consolidated Virginia mine for the month of February was \$1,205,390. This and the payment by the company of a dividend of \$10 per share, speaks well for the bonanza mines.

Industrial Items.

THE Portland iron works of Messrs. Moynihan & Aitken are just finishing the largest steam boiler ever built on this coast, and as large as has ever been built in the United States. It is 14 feet 8 inches in diameter, 16 feet across the front, with a chimney 10 feet in diameter and 12 feet high, and stands from the ground 25 feet 8 inches high. The length of the boiler is 19 feet 4 inches and it will weigh 100 tons when in position in the steamer "Senator." The iron is 3/4-inch and the rivets are also 3/4-inch, and the tensile strain on the iron is 60,000 pounds to the inch.

THE Kern county Courier of March 6th, says that the Hyde steam wagon, although not yet perfected in all its details, is proving a great success. It is now engaged in plowing and is doing splendid work. On Monday it plowed thirty-one acres in splendid style, and when every little fault of construction that experience points out is remedied, it will do much more. The cost of running the machine that day, or of doing this amount of work, including interest, wear and tear, etc., was \$25—a vast saving over the old method of plowing.

ACCORDING to the Shasta Courier, Judge Beatty, of Sacramento, has purchased 1,200 acres of coal land from Peck & Kincaid, whose coal lands are situated on the head of Oak run, Shasta county. The work of developing these mines will be immediately commenced, and a large force of men will be employed. The coal extracted will be shipped to Sacramento, as soon as shipping facilities can be arranged.

IN Alameda county, some 24 miles south of Oakland, there are 400 acres of land devoted to salt making. In winter the sea water is let in, and in June it is gone into the clouds, leaving the salt behind. The annual yield is 7,500 tons, and the table salt there made brings \$10 per ton, while the cost of making it is \$6 a ton. Forty men are employed in the business on these 400 acres.

A NEW irrigating district is soon to be formed under the Bush irrigation law, which will include Anaheim and the surrounding country to the extent of 12,000 acres. The water will be brought from Santa Ana river. This will be the second district formed under the new law, and will bring in all about 26,000 acres under irrigation.

THE Vallejo broom factory is now turning out fifty dozen brooms a day. To accommodate their interior customers they have combined with their business a full line of wood and willow ware imported by them from the East.

A BURNING gas well in Butler county makes summer weather in the neighborhood. The trees are budding and the grass growing in the charmed circle of its influence.

MR. AYRES, lately from St. Johns, N. B., has purchased the mill and water privilege of C. P. Traber, of Ukiah, and expects to erect a woolen factory there during the coming summer.

THE new machinery for the Capital woolen mills, Sacramento, is daily expected from the East. There will be about three car loads of it, of the most approved pattern.

MR. F. C. CHASE, while boring a well at the Findley ranch, near Wheatland, recently, discovered what are considered infallible signs of coal.

THE narrow gauge company of Salinas and Monterey has just received another locomotive from Philadelphia, at a cost of \$8,000.

General News Items.

OFFICIAL reports from all the railroads in Minnesota show only 2,340,000 against over 5,000,000 bushels last year. Well posted grain dealers estimate the entire wheat crop of last year at 21,000,000 bushels, and as over 16,000,000 bushels has already been shipped, there remains but little over 3,000,000 bushels in the hands of farmers.

WASHBURN & Co.'s new grade into the Yosemite Valley, from Clark & Moore's, a distance of twenty-four miles, will be completed about the 15th of next month. When finished this grade will be the finest one leading into the valley, as tourists can travel with as much ease and comfort as if on our valley roads.

THE THIEVES are getting smart in Vallejo—they have taken to stealing gardens. A resident of that place arose the other morning to find the shrubs, flowers, roots and hulloes which had adorned his premises the day before, vanished, and what was a garden, transformed into a desert.

THERE is no prospect of a speedy settlement of the difficulty between the Pennsylvania and Baltimore & Ohio rail road companies. In the meantime the public are being benefitted by the reduction of freight and passenger rates.

AMONG the important Pacific coast bills which passed Congress at the end of the session and have become laws was the bill providing for the coinage of twenty-cent silver pieces, to be a legal tender to the amount of \$5.

THE forty-third Congress adjourned on the 4th inst. The extra session of the Senate called by the President will probably continue until the last of the present month.

SECRETARY Bristol has directed the retirement of \$1,385,000 of legal tenders, being 80 per cent of the National Bank circulation issued under the new Currency bill.

OVER forty persons who have died in St. John, N. B., this winter, have been temporarily interred in the snow which lies in such quantities as to prevent the opening of graves.

SISSON, WALLACE & Co. have orders for 1,400 or 1,500 workmen on the Grass Valley and Colfax road, and the southern railroads of the State. Here is a chance for men wanting employment.

A RUMOR comes from Paris to the effect that there is great difficulty in preventing young King Alfonso of Spain from abdicating in favor of Duke De Montpensier.

RAILROAD travel has been very much impeded in the Eastern States by the snows of the past week. In Michigan most of the roads have suspended operations entirely.

THE Reporter has an article on "apathetic Napa," in which the apineness of that county is complained of. Railroad communication is needed to gain access to the outside world.

A colony of Tennesseans, among them Gen. Forrest, will soon arrive in Los Angeles county, where they intend settling.

THE President has nominated Godlove S. Orth as Minister to Austria and Horace Maynard as Minister to Turkey.

AT Pacheco a company has been organized and is now engaged in preparing the ground for planting sixty acres of tobacco during the present season.

THE trees around the Vallejo City park which died during the present year have been removed, and good live trees planted in their places.

Large quantities of grape-vine cuttings are now being shipped from San Jose to San Buenaventura and other points in Ventura county.

THERE are several grain and hay merchants at South Vallejo who are just wild because the cows are permitted to run at large.

MANY of the heavy grain dealers in Santa Clara county, who have held their grain since 1873, are now disposing of it.

MANY of the Oregon farmers are changing their large pastures into fields of growing grain.

THE Yolo Mail threatens to start a new daily in Woodland.

Agricultural Items.

NEGOTIATIONS are now pending between the settlers in the vicinity of Whetstone and the Fresno canal and irrigation company, with a view to securing the immediate construction of a branch canal to that vicinity. The company propose to construct a canal immediately, conveying an abundant supply of water, provided a sufficient number of persons can be found who will bind themselves to purchase water at the rate of one dollar per acre per annum.

THE COMING STRAWBERRY SEASON.—In about two weeks we may expect the opening of the strawberry season. Present indications warrant sanguine expectations on the part of the vast army of strawberry eaters. Some have predicted a surplus, and that the growers would not receive pay for labor and investment. It is to be hoped that this will not be the case; and we have faith that the expected increase of supply, will create a corresponding increase of consumption.

ABOUT GREEN PEAS.—We have just received a note from a gentleman of Harrisburg, Alameda county, asking: "Whether there are any green peas in market, and if so what is the price?" Of course there are. Green peas have been in the S. F. market nearly four weeks, and are now selling at 5 to 5 1/2 cents per pound by the sack.

THE Contra Costa county people are, it seems from the Gazette of the 27th ult., bound to wage an unremitting warfare against the squirrel until their extermination is assured. The Gazette says: "We know that we must destroy the squirrels or ultimately abandon the land to them, and the sooner we determine to do one or the other the better and more profitable it will be for us."

ON the Cosumnes bottom, says the Sacramento Agriculturist, heavy crops of corn are raised; after the water has passed off, a heavy sediment is left of richness, which, when powdered, is valuable for corn, pumpkins, potatoes; large numbers of hogs are raised and fattened every year.

A CORRESPONDENT of the Tulare Times writes from Linn's valley that the farmers in that neighborhood have about finished sowing all the land they intend to cultivate in grain or hay, and are now busily engaged in preparing their land for a more extensive potato crop than ever grown in that valley.

THE Southern Californian advises farmers to plant more grain this season and stop importing from San Francisco. It will require 100,000 sacks of grain this year to supply the Cerro Gordo freight company alone.

THOUSANDS of fruit and shade trees have been planted in Hollister and environs within the past few weeks.

FARMERS in Tehama report the crop prospects along the southern border of the county as most cheering.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

GEORGE WILSON, formerly contributor of the MINING AND SCIENTIFIC PRESS, will please address this office.

PATENTS & INVENTIONS

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., March 9, 1875.

FOR WEEK ENDING FEB. 23, 1875.

ABSORBING AMMONIA GAS IN WATER.—John A. Beath, S. F., Cal.

GRAIN SEPARATOR.—Josiah H. Looke, San Jose, Cal.

COMPOUND FOR THE PREVENTION OF SOALERS IN STEAM BOILERS.—John H. Pitts, Oakland, Cal.

GAS METER.—Jacob Radston, S. F., Cal.

RAILWAY CAR AXLE.—Samuel L. Harrison, S. F., Cal.

FERTILIZING COMPOUND.—Chas. H. Hoffman, S. F., Cal.

SADDLE TREE.—Pemberton B. Horton, S. F., Cal.

WAGON BAARE.—Robert J. Knapp, Half Moo Bay, Cal.

SOREW PROPELLER.—James H. Loftis, Oakland, Cal.

RE-ISSUE.

FOR TEAS.—Williams, Blanchard & Co., S. F., Cal.

"The patents are not ready for delivery by Patent Office until some 14 days after the date of issue. Copies of U. S. and Foreign Patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible."

THE San Juan Times says: "The people and around French Corral complain of the great scarcity of water for mining purposes. The Milton company have to distribute the supply of water among so many mines that they only retain enough to keep their own mines at work about half the time. This has been, thus far, a poor season for the miners, and unless we have very heavy rains higher in the mountains during the months of March and April, fears are entertained that even miner in this township will be compelled to the first of August to cease from work."

THE Yreka Union learns that the miners on the Klamath river are busy making preparations for a vigorous prosecution of their claims the coming season, which, owing to the small quantity of water that has fallen this winter promises to be a longer one than usual with them.

"I'LL RISK IT."—"That cough will kill you, if you neglect it," said a New York merchant to one of his partners about nine weeks ago. "Try Hale's Honey, Horchond and Tar," he added. "It has cured my wife of just such a cough as you have, and I believe would cure you." "Nonsense, my dear fellow," was the reply, "mine's not a cemetery cough. It will stay of itself. I'll risk it!" He did "risk it," and is present apparently in the last stage of Chronic Bronchitis. He is now taking the remedy he scoffed at, and it relieves him; but it remains to be seen whether it is not too late to effect a cure. Pike's Tooth-Ache Drops—Cure in one minute.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Prices Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

HORIZONTAL FLUME,

Patented April 1, 1873.

TREADWELL & CO.'S

(IMPROVED)

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call particular attention to the graceful design and simple mechanism of this Engine Boiler; the form is not only pleasing to the eye, but is, also, that which secures the greatest strength and rigidity with a given amount of material. The Boilers, which are of the upright tubular type, are made of the best material and are riveted with the best workmanship. The heating surface and area of grate are in excess of the quantities usually allowed for the same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is mounted on a separate frame, so that the boiler can be overhauled by conducting to the engine, without the necessity of being at the base of the boiler. The high speed which is necessary for economy of fuel. All parts are easily accessible—a great advantage. The engine can be detached from the boiler and run independently. If required, its main parts are simplicity, safety and small repair or machine shops, or for hoisting, where a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut-off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine.

Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.

(Covered by Letters Patent of July 2d, 1872, and recent applications.)

Containing a sizing apparatus, (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having 5 sieves, each row concentrating according to specific gravity the spacial size automatically fed into it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d-class ores into 1st-class ore of perfect cleanliness. It thoroughly separates native gold or copper from quartz or any other loose matter; galena and silver sulphurets from pyrites, barite and quartz; and pyrites from quartz.

Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

Hydraulic Mining in California.

No. 17.

The Grizzly.

This word in the strange nomenclature of the California miner means a grate or framework of parallel iron bars, with interstices, which is used here and there in the line of sluice boxes to throw large pebbles or stones out, and to permit such particles only as can pass easily through the interstices between the bars to be carried farther along in the sluice boxes. Wherever a grizzly is applied, a drop of a few feet is necessary; since the material which can pass through must be collected in a box below and thence carried away by a power section of sluice boxes. The construction of grizzlies is of use only where the stones to be discharged over the grizzly can be thrown down a steep embankment. When this is the case, the sluice boxes can be relieved of a great quantity of useless material.

To illustrate, we will suppose that a precipice of 40 or 50 feet exists close to a drop box, so that any material thrown outside of this box would tumble down the precipice. This would give a favorable chance to apply a grizzly, which would have to be done by attaching a frame work of strong iron bars, connected iron rails are excellent, to the bottom of the sluice box, which discharges its contents into the drop box, and to lead this grate with fall of about 30 degrees across the drop box and toward the precipice.

The iron bars or rails would have to run the full width of the sluice box, six inches apart and parallel with each other, towards the precipice, and all boulders larger than six inches in diameter would be discharged. On both sides of this grating planks must be fixed to prevent any of the stones from escaping sideways.

Hydraulic Nozzles.

The observant miner early perceived that if a certain amount of gravel could be washed with a certain quantity of water, double the quantity of water would wash from three to four times as much gravel without increasing the expense for labor in proportion. Greater quantities of water and enlarged hydraulic nozzles were therefore introduced, and he latter became very soon the object of imitative speculation, which resulted in the successful production of the very ingenious hydraulic machines.

The first improvement was a flexible iron joint, Fig. 1, formed of two elbows, working one over the other, with a coupling joint between them. These elbows were called goose-necks.

This invention was a decided improvement, though it showed some serious defects. The abrupt turn of the elbow broke the force of the water to a great extent; the upward pressure made the joint c, hard to move, and when the pipe was turned horizontally the hose part could often bend a little too far and the reaction would cause the pipe to "buck" or fly round in a contrary direction. The same reaction would also often occur in elevating or depressing the pipe.

The next improvement was Craig's Globe Monitor, Fig. 2. This invention consists of a globe or globe, with an opening on one side, into which enters the main supply pipe, and one on top, out of which an elbow joint protrudes. One end of this elbow is attached to a socket which revolves on the interior of the globe, and at the same time creates a water tight joint. This joint enables the operator to change the direction of the stream from point to point at pleasure. To the other end of the elbow is attached the discharge pipe, which may be of any size desired. The ball revolves entirely round horizontally, and up or down at an angle of about 40 degrees.

The next machine introduced was Hoskin's Dictator, in which the parts constituting the joint work with an external instead of an internal connection; that is, the pressure of the water, instead of forcing the parts of the joints together, tends to force them apart, and the

joint, to keep it from leaking, is provided with an elastic packing. Both rotary and vertical motions are facilitated by the peculiar construction, wheels reducing the friction on the former, and the later turning on pivots. This joint is still much used; the only objections to it is the unnecessary loss of power on account of the elbows being too abrupt.

Another machine under the name of Watson's Champion, similar in design to the last

the rolls themselves. A piece of rubber pecking placed between the flanges of top and bottom elbows, makes the joint tight by the pressure of the water against the ring. In the outlet or top elbow is a knuckle joint, which permits the up-and-down motion of the discharge pipe. It is a concave surface fitted to a convex one; the concave has an opening for the pipe to pass through. The pipe is screwed into the convex surface and will move up and down, while the

mentioned, was introduced, but denounced as an infringement on the Dictator, and put under injunction.

Another new machine entered the field under the name of Knuckle-Joint and Nozzle, Fig. 3, invented by Mr. F. Fisher, of Nevada county, California, consisting of two elbows, placed in reverse position when standing in right line, but made to revolve by a ring in which there is a series of anti-friction rolls, the ring being slipped down over the top of the lower elbow, and then held in its place by a flange bolted to the top of the lower elbow. The ring is then bolted to a flange on the top elbow, thereby connecting the two, and at the same time leaving the top elbow free to move around in a complete circle. When the water is let into the elbow the pressure biases the rolls in the ring up against the flange on top of the bottom elbow, allowing the top elbow to move around easily and without any friction, except that of

the rolls themselves.

The elbow end knuckle joint are made of cast iron from five-eighths to three-fourths of an inch thick. The discharge pipe is made of No. 16 iron, eight feet long, with cast iron nozzle. The machine is operated by a lever 10 or 12 feet long, with two arms, and attached to the top elbow by trunnions. A lever is pivoted to the top of the upper elbow and attached on one end to the discharge pipe by a strap inclosing the pipe, and provided with two rolls on the top for the lever to slip on. At the other end it is connected with the operating lever by a short upright lever, made to work loose on its joints. Thus the up-and-down motion is imparted to the discharge pipe by the rise and fall of the operating lever. By moving it to the right or left the whole machine, except the bottom elbow, is moved. A little device is attached to the lever to hold the discharge pipe

in position when the water is off. It is a catch working in a ratchet on the top elbow, attached by a rod running out on the lever, so that the operator can put it in or out as the case may be.

The pipe stands firmly in place when the water is on; the operator, standing at the end of the lever, can easily direct the stream to any point—good execution being done at a distance of 200 feet from the bank, thus securing safety of life from caves, which are so frequent and so often fatal, where small streams are used against high banks. These machines are made to throw streams of from four to seven inches in diameter.

The Little Giant, Figs. 4 and 5, invented by Mr. R. Hoskin, of Dutch Flat, Placer county, is claimed to combine all the requisites of the hydraulic nozzle.

Simple in its arrangement, it is easily managed, and an additional pressure of water does not interfere with its motion, as the connections, or joints, instead of being forced together, are forced apart by such a pressure. The avoidance of abrupt angles in its construction makes the Little Giant approach nearer to the straight line than any other hydraulic machine so far introduced. Upon the strength of this fact, it is claimed, and apparently with good reason, that less resistance is offered to the flow of water by the Little Giant than by any other hydraulic apparatus, and that by it, therefore, not only a greater quantity of water, but also a far more powerful stream can be discharged.

The joints, being packed with leather, are dependent on the packing for tightness, and are thus preserved from wearing or grinding out. To prevent this rotary motion of the water, produced whenever the elbows are turned different ways, the "rifle," Fig. 6, composed of radial plates, is inserted in the discharge pipe. These plates force the water to issue in a straight line from the discharge pipe, and thus prevent the scattering or breaking up of the stream, on the solid and columnar shape of which so much of its effectiveness depends.

The Little Giant has been worked with six-inch nozzle under a pressure of 435 feet.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

The Botany of California.

When the work of the State Geological Survey was suspended by the Legislature, no provision was made for the publication of what had been gathered in the department of botany. A good deal of labor had been done in this direction, and there was great disappointment when it was learned that the matter would not be published, for want of means. Since the survey was suspended, several efforts have been made to publish the material, and the last one was successful. Prof. Gilman, late President of the State University, with the co-operation of other citizens, has received subscriptions to the amount of \$5,000 for this purpose.

This is cause of great congratulation, as the California flora develops some characteristic species novel and interesting, exciting the attention of all students of botanical science. The publication is now secured through the exertions of Prof. Gilman, at whose request the following named gentlemen have contributed the necessary funds to stereotype the work: Leland Stanford, Henry Pierce, R. B. Woodward, Lloyd Tevis, D. O. Mills, J. C. Flood, John O. Earl, Wm. Norris and Charles McLaughlin. These gentlemen are not known to be scientists and do not appear to be actuated by any special or personal motive. Honorable mention should also be made of Professors J. D. Whitney, Asa Gray, and Watson of Harvard University, and especially of Prof. W. H. Brewer, of Yale College, for their personal devotion to this work, without any pecuniary compensation.

At last pay-day, the miners of the Crown Point mine contributed \$921.50, the Belcher, \$239.50, and other sources \$119—total, \$1,280—for the widow and family of Mr. McLaughlin, formerly a miner in the Crown Point, who died some two weeks ago.

CORRESPONDENCE.

Mexican Mines.

The Native Silver District of Morelos, State of Chihuahua, Mexico.

(Written for the Press by A. E. Koels.)

Everybody has read in books or knows by hearsay of the wonderful riches which lie hidden underneath the famed soil of the land of the Aztecs; yet the number of those who by personal and practical experience are enabled to form a correct idea of the truly vast extent and astounding variety of Mexico's mineral resources, is certainly very limited.

A long residence in that country having made me intimately acquainted with it, more particularly with the State of Chihuahua, I propose to give in the following lines a description of one of its most interesting mining districts, which in my opinion offers a very fair field for profitable investment of capital.

Morelos

Is, besides the adjoining district of Batopilas, whose many great bonanzas in former times, and again in our own days, shed such brilliant lustre over its name, the only one within the confines of Mexico; end, so far as known—except the famous mines of Los Caracoles, in Peru—in the world—where the native silver is found to form the most important part of the ores, hereby distinguishing itself from all other silver regions.

While the mines of Batopilas have been worked for fully two centuries already, those of Morelos only became known in the year 1826, but at once attracted considerable attention.

Its Situation

In the south-western part of the State, is in 27° 30' north longitude, and 107° 26' west latitude from Greenwich, about ninety leagues southwest from the city of Chihuahua, and the same from the nearest port on the Gulf of Cortez (Aguila) in a direct eastern line, in the very heart of the Sierra Madre mountains, which attain here an average height of from six to eight thousand feet above the sea.

The Mountains

Which enclose the extremely narrow gorge, hidden in which lies the town of Morelos, rise on all sides, in steep inclinations of from 35 to 45 degrees, up to three and four thousand feet above the bed of the creek flowing at their base, and emptying into the Rio de San Miguel, the valley of which forms a tremendous break in the chain, highly interesting as to its geological features. In fact, this whole section, having hitherto been but very little traveled over by intelligent observers, remains as yet almost entirely unknown, although abounding in points of terrific grandeur and nature's wonders. Deep ravines furrow them on all sides, and dark colored rocky cliffs, in the most fantastic shapes, crown everywhere their summits; while the most luxuriant grasses, green all the year round, carpet them wherever the soil allows it under the shadow of gigantic pine trees, followed lower down by manifold oak and madroña trees, these again to the gorges beneath by a thick growth of high, thorny bushes, and giant species of cacti.

The Climate,

Warm and pleasant during the winter months, gets, however, due to the shut in location, extremely hot from March to October; consequently many cases of fever occur (*calentura*), but seldom of a very aggravating form.

The Population,

Like that of all mining towns the world over, changes with the temporary state of the mines; increasing rapidly as soon as the report of a bonanza goes abroad, and as quickly dispersing again whenever this ceases to give employ or chance to gain. At present it may not pass a few hundred, who, for the most part, live in that miserable state so indicative of poverty and idleness; yet seeming to be an unchangeable institution of the country.

The Principle Articles of Consumption

Are all brought from over the mountains on mule pack trains, either from the towns of Alamos, El Fuerte, Sinaloa, Parral, etc., or the small Indian ranchos which lie scattered in the gorges, or over the mountain sides of the Sierra, and are partly cultivated by the numerous half civilized tribe of the *Tarahumaris*. The freight paid for a mule load of 300 pounds (*carga*) from any of the above named towns amounts to from \$6 to \$9; consequently everything is dear. Corn (*maiz*) for instance, always ranges from \$5 to \$8 per fanega (12 almudes); brown beans (*frijoles*) from \$8 to \$12; flour, from \$18 to \$26 the carga of 300 pounds; salt, from \$7 to \$10 per fanega; lard (*mantequilla*) from \$6 to \$9 per arroba of 25 pounds; tallow (*sebo*) from \$5 to \$7 per arroba; brown sugar (*panocha*) \$24 to \$30 per carga of 600 pieces, etc.

The Geological Formation

Which comprises the greater part of the district resembles more or less that of Batopilas. Speaking in general terms, granite, often complicated with granite (*bucohuatl*), or syenite (compact felspar with hornblende), with transition to porphyry, constitute the principal

mass of the mountains immediately to the south and east of the town. Granite may be said to dominate to the west and north; in many parts conglomerate either underlies or overtops the same. Stratified rock I have noticed in but very isolated and little extended locations. Limestone and slate formations are more prominent to the south and east, more distant from the center of the district. A very noteworthy and important circumstance presents itself in this, that the lodes carrying the native silver are almost exclusively confined to those ridges of mountains which lie northwest of the town, or the dividing creek, while the opposite ranges are filled with veins carrying argentiferous lead, fahl ores, and such in combination with copper. Certain hills abound equally with splendid indications of gold; in fact, a number of such veins are known; none of them, however, have as yet been worked, for want of capital and enterprise. I have seen some of the latter ores which were very rich indeed.

The whole mountain ranges belonging to the district seem in fact to form an inexhaustible deposit of precious metals.

The Mineral Lodes

Are for the greater part very formal and true fissure ones. Those of the native silver in the neighborhood around Morelos, generally with a strike from north to south, deviating more or less, and a medium dip of eighteen to twenty degrees to the west. Their matrix, differing somewhat from that of the Batopilas veins, carries far less calc spar (*espato calizo*), seldom quartz or flint, but consists more of slate.

Like their celebrated neighbors, however, they do not, as a rule, crop out very wide on the surface, nor do they attain below the dimensions of other classes of ore veins, but in few instances widening out over two yards. Their great redeeming and distinctive feature lies in the peculiar richness of the ores, a comparatively small stretch of which often gives a very large result. Their average width is from three quarters to one yard. When they enter into ores they will often expand to beyond that, sometimes carrying them disseminated all through their body; or others more concentrated on the lower or the upper wall, (*respaldo alto o bajo*). As in all other metal-bearing veins, the ores are found in stretches of more or less horizontal or perpendicular extent, with barren spaces between them. These have to be thoroughly prospected in order to find the rich spots.

The Ores

Are, as already stated, formed of various combinations—sulphurets, often intermixed to a great extent with, and merging wholly into native or malleable silver—their great distinctive character.

Like Batopilas, nature seems to have indeed particularly favored Morelos with a remarkable show of this latter metal, in an entirely or almost pure state, greeting the eye often with a most brilliant white color (although of this more in B) and of very curious and interesting shape, so that many pieces might be readily taken for works of art rather than of nature, and are eagerly sought for as precious specimens for embellishment of mineral collections.

These ores are classified as first, second, third and fourth class; the latter showing but little if any silver at sight, and is known as *aqueous*.

The key of them ranges from \$56 to \$100 per ton of 2,000 pounds for fourth class; from \$100 to \$300 for third class, and from \$600 to \$1500; and from this to perfectly solid silver of \$32,000 per ton in value.

The Virgin, or Native Silver,

Occurs mostly in the shape of massive silver, which does not break, but must be hammered or chiseled out of the matrix, (*plata maciza*.) Wires—of more or less thickness, (*plata alamburada*.) Nails—more or less thick, separating by pounding, called *broza*, when very fine and near together, gives from one-third to two-thirds of the weight of the stone in silver, (*clavos de plata*.) Leaves—like thin sheets, (*plata de hoja*.) Lumps—generally enveloped in a soft clayish crust; often of one-half or two-thirds of its weight in silver, (*bola de plata*.) Pieces or grains, like the metallic gold.

The Beneficiating

Of this metal, or its ores, is done in a twofold way; by means of regular smelting furnaces, (*horno de fundicion*) of not very improved pattern, or by the application of quicksilver, by the old Mexican or Patio process, (*amalgamacion*.) The bullion resulting from either is refined in more or less crudely constructed cupel ovens, (*vaso de finacion*.) The actual loss produced by any of these manipulations is however much less than might be readily supposed from the often very primitive arrangements.

The ores of the fourth and third class, often being crushed by hand and means of heavy stones, or in the few existing regular mills, (*hacienda de beneficio*) by water-power machinery, are ground to a fine pulp in common stone built mills, (*tahona* or *arastro*) which generally grind from nine to 1,800 pounds (three to six cargas) during 24 hours, then taken out, carried to the Patio or open flag laid space, and here piled up in heaps (*montón*) of from four to eight tons each (30 to 60 cargas of 300 pound.) After being spread out, salt, iron or copper pyrites, (or sulphate) quicksilver not get mixed with them in their due proportions, ascertained before by assay or trial, and repeatedly trodden over by men or beasts, but very thoroughly each time, and the amalgamating process left entirely to the influence of the sun or atmosphere. Frequent tests with the horn-spoon show how this mysterious

process progresses and when it terminates. As soon as no more silver is taken up by the quicksilver, the entire mess gets washed out (*lavar*) in a reservoir (*pila*) prepared for the purpose, the amalgam carefully separated by kneading it, and after letting the earthy matter run off, the metallic particles or tailings (*polvillos*) are concentrated (by frequently throwing water on them), for future separate treatment. The amalgam is then burnt to separate the quicksilver from the silver and this latter refined (*apinar*.) The loss of the former during this entire process depends in a great measure on the care taken.

The first and second class ores are simply pounded with a hammer or a heavy stone, until the metal (native silver) concentrated in it gets as much as possible separated and clean of adhering matrix. It is then taken to the furnace (*horno*) in quantities of generally 25 pounds, to be smelted down. These give from \$250 to \$350 and more in silver. The resulting from the crushing is ground in the mill (*tahona*) to a flour-like state, washed out and its metallic parts treated in the same way as the foregoing, when they will produce a similar ley. What after this remains of parts is again ground together with the lower class ores and beneficiated along with them in the Patio. The tailings are subjected to a careful roasting in a reverberatory furnace before they are taken to the Patio, there to be treated with quicksilver, or are sometimes taken at once to the furnace.

The average expense for beneficiating one ton of third and fourth class ore (not included the cost of quarrying and delivering at the mill) may, while the price of quicksilver keeps at \$1.50 to \$2 per pound, be set down at from \$14 to \$20.

The Cost

of the working in the mines differs of course with the class of rock enclosing the lodes. The average price per yard of ordinary dimensions, when drifting with black powder, ranges from \$30 to \$35. Powder sells at \$7 to \$8 per 25 pounds (*arroba*.)

The Wages

Peid in the district to the workmen in the mines are comparatively low. A foreman (*minero*) earns from \$9 to \$12 per week, a miner (*barratero*) five to six reales (bits) per day's work of two blast holes 18 inches deep each and to charge and fire them off; a man who carries the rubbish, and the metal out of the mine (*tenatero*) four reales; a boy for all work (*zorro*) two to three reales; a watchman (*guarda-mina*) \$4 to \$5 per week; a man to attend to the mules (*muelero*) \$3.50 to \$4 per week; other workmen outside the mine, at the ore mill cost from four to six reales per day.

The Extent of the Claims

Or *pertenencias*, corresponds to that prescribed by the old Spanish mining laws (*Ordenanzas de mineria*) still in force in Mexico, which allows 200 varas (600 feet) measured off along the lode on the surface, by 100 varas (300 feet) in width, laid off at option on either side of the lode, running down perpendicular to the center of the earth (if needed) and enclosing an indisputable property everything contained in this parallelogram. A so-called company's claim (*perlenencia de compania*), however, is allowed to comprise four single *pertenencias*, therefore equal to 800 varas (2,400 feet) in length, by 100 varas in width. But the discoverer of a new lode is entitled to two single claims for himself. In regard to the

Number of Veins

Morelos may be said to compare very favorably with any of its surrounding districts; yet it seems that by far the greater number of these lodes which carry native silver, are concentrated in a mountain northwest of the town, and known as *El cerro de San Anastasio*, which in all its parts seems to be traversed by them, and in some spots running out from towards San Joaquin or independent hills divided by the deep gorge known as *La Corcovada*.

Few of them have, however, been actually worked, and but two over 100 yards in depth, most of the others from 10 yards only to hardly over 50 or 60. They may therefore justly be called "virgin" ones. The reason why must be looked for in the general lack of capital and the unstable state of the country, formerly nipping at all enterprises in the bud. Almost all the lesser work had to be done by *gambuzinos*, who discovered the lodes, or by men of small means, both of whom confined themselves merely to picking out what metal they were fortunate enough to encounter on or near the very surface, but had no means nor courage to follow up as soon as barren parts of the vein cut their "bonanza" temporarily off.

Many of the lodes may indeed not prove remunerative, although their surface indications are promising; still, this question can in the end only be solved by the employment of at least a certain amount of capital and work on the mines, which would justify the opinion. As a rule, verified by actual experience, the larger body of ore may not be looked for until a depth of from 30 to 40 yards has been attained, with corresponding exploring drifts. The deeper, the more constant and of richer ley they will show, while near the surface, although often extremely rich and running into solid silver, they will hardly ever be extensive.

The General Opinion

Among the mining population is, and this corresponds with my own observations, that, "if money be invested in any of the better class veins, selected with circumspection, and lying in good mineral ground (*panino*), nothing will be lost." The main condition for success is,

of course, besides the good lode, a proper and economical management of the business, doing away with any and all unnecessary or fancy expenses which have ruined the most of the American mining enterprises in Mexico in former years, but few of them having been conducted by men of experience, or who were willing to forego conveniences of life which they had been used to. Above all, leave all costly machinery alone, until the state of the mine imperatively calls for it.

In my opinion, a working capital paid in or otherwise secured, of from \$15,000 to \$20,000 is sufficient, if expended with care, to open one of these above mentioned mines, or bring it into a satisfactory state.

A number of them are held by private parties, either by actual possessory papers, or by denouncement or re-denouncement, a majority of whom would be willing to part with them for a corresponding remuneration, they lacking the means to prosecute the work in them. Other mines, however, have at present no owners and are open to denouncement. One like the other needs exploring to prove their value.

The first of all these native silver mines ranks the great

San Gil Mine,

Discovered in 1826 by Gambuzinos, among them a most remarkably gifted prospector, Don Juan N. Avila, who at first took up four independent claims upon it. Beginning with rich chlorides (*bodagones*) and native silver, this latter soon became predominant, for considerable stretches running into massive metal and for a long time continuing to give forth great treasures, so that often \$40,000 and \$50,000 were taken out in a single week. In fact, the virgin silver was actually found cropping out in more than one place along the lode, which crosses the southeast slope of the San Anastasio hill, in a southeast to northwest direction, and a west dip of 20 degrees.

The ores of it are very peculiar, containing iron pyrites, among them very conspicuous the so-called "ruby-silver" ore, which, especially in a certain part of the mine, therefrom surmised "Sangre de Christo," was found in such quantity and of such blood-red color, that the entire vein seemed to be painted. The most beautiful and perfect crystals of it have frequently been sold for very high prices.

The great deposits of metal seem to have extended more in a south direction and about 60 yards downward. No regular accounts of their product was kept by the first owners, still it is known that it must have been many millions. Being but illiterate men they, with the improvidence peculiar to their class, spent their fortune as fast as it came out of the bowels of the earth, until, when the ore body finally gave out, they were obliged to sell out to a gentleman named Don M. Ochoa, who united the four claims into the present one. His heirs still own and work the same under the present management of Sr. Don Francisco Ochoa.

The perpendicular depth of the workings comprises in no part 120 yards, although in the places connected, galleries extend over 300 yards in a longitudinal direction. The metallic silver of this lode is very pure, hardly losing two per cent., and often met with very brightly polished end white.

The mine may be said to be virgin yet, and every sign is highly favorable for again striking a bonanza after passing the intervening barren layers of the lode. A tunnel being started to cut it below the old bonanza parts gives already very promising hopes; equally so a gallery being driven to the south in virgin ground. The present owners having become weakened by other enterprises, have for several years only been able to work the mine with a mere handful of men. The days of new prosperity seem, however, to be near, if I may judge so from ores which I saw myself coming out of the mine on the very day before I left Morelos in December last.

A number of more or less parallel running formal lodes enter the claim, laying west of the San Gil; none of them here, however, been worked to any extent, all giving, wherever picked at, on or near the surface, very rich silver and chlorides. The mineral country is everywhere excellent, the country rock partly granite, partly diorite and syenite.

[Concluded next week.]

OPEN ORE MARKET.—A new enterprise, in which all miners will take a lively interest, is the crushing and sampling work now in course of erection on the corner of Third and Argentine streets, by Melliss & Morris, a new firm, but well acquainted with the wants of the miner, and having abundant means and knowledge to carry their project to a successful issue, and, at the same time, to supply a want long demanded in our community by parties having ore to sell of all grades and qualities. In other words, an open market, in which the ore is sold to the highest bidder for cash, after having been crushed to the required fineness and carefully sampled and assayed; bottled and sealed samples having been previously distributed among the buyers, somewhat after the plan so successfully adopted in Salt Lake and other large ore markets. By this method the miner can be in no doubt as to whether he has received the full value of his ore; and Messrs. M. & M. propose to go still further and, in the event of a "slow" market, to themselves take all ore sent to the mill, at full prices, for shipment to Europe. In addition, they will be at all times ready to make cash advances on well known ore as soon as delivered at their mill which, it is expected, will be ready for business by the end of the coming month.—*Colorado Miner*.

MECHANICAL PROGRESS.

New Uses for Copper.

Dr. Knuzel, whose name will be recalled as a joint discoverer with M. Montefiore-Levy, the well known phosphor-bronze, now announces the additional discovery that when phosphor-bronze is combined with a certain proportion of lead, the phosphorized alloy, when cast into a bar or bearing, segregates into two distinct alloys, one of which is hard and tough phosphor-bronze, containing but little lead, and the other a much softer alloy, consisting chiefly of lead, with a small proportion of tin and traces of copper. The latter alloy is almost white, and, when the casting is fractured, it will be found nearly uniformly diffused through it; the phosphorized alloy forming as it were a species of malleable sponge, all of whose cavities are occupied by the soft metal alloy segregated from it. This phenomenon of the segregation into two or more alloys, of combinations of copper with tin and zinc, has long been known, and the fact that such separation is generally passive, and not equal throughout the mass, it has been a source of annoyance to the founder. Dr. Knuzel, however, seems to have succeeded in causing the segregation to take place in a uniform distribution throughout the casting. It has taken advantage of the properties of the product which he obtains in this manner, to construct therefrom bearings of railway and other machinery.

In heavy bearings, such as those for marine engines, the valuable properties of Babbitt metal, and similar anti friction alloys, are well recognized; but these being generally soft, are subjected to the grave objection that where they are subjected to considerable pressure, or even moderate pressure accompanied by continued vibration, they become distorted in form, and fail to sustain the journals in their proper position. The device is, therefore, resorted to by the machinist, of casting a hollow cage of lead metal, of proper form, for the intended bearing, the cavities of which he then fills by casting into them the soft metal alloy, which thus forms the actual rubbing surface of the bearing. The hard metal cage supports the metal within, and prevents its distortion or escape, save by surface abrasion. Dr. Knuzel claims to effect the same result by the peculiar constitution of his new phosphorized alloy for bearings. This forms its own supporting cage, for the soft bearing metal, which, according to the out-set, separates from it in the process of cooling. He claims that these bearings combine the very small friction and abrasion of the journals, with the firm resistance to pressure and stability of form of rings of hard metal. The test of practice can decide the value of these claims, though they seem very plausible.

In relation to the above see article on this page—"Brass vs. Phosphor-Bronze Bearings for Rolling Mill Use."

MICA SUBSTITUTE FOR STOVES.—A correspondent writes to the *Iron Age* as follows: Sir—The illuminating principle in stoves has become so thoroughly established, and the constant demand for mica has become disproportionate to the supply, is it not possible for one of our chemists to produce some chemical substitute for the same that shall be cheaper and as durable? Illuminating stoves to the household are like pictures on the walls, refining and civilizing in their influence and tendency, and so great a boon to mankind should not be jeopardized by fear of any failure of the supply in an article that possesses the quality of much pleasure and health-giving comfort. Would this suggestion be within the possibilities of chemical combinations, a liberal reward will be paid by the stove manufacturers of the country.

The editor of the *Gas Light Journal* calls attention, in connection with the above, to a communication in reference to the same idea published in that journal, April 16th, 1874, wherein a beautiful device for this purpose was given by Dr. A. A. Hayes, of Brookline, Mass.

BRASS VS. PHOSPHOR BRONZE BEARINGS FOR ROLLING MILL USE.—A correspondent at Pittsburgh recently wrote to the *Scientific American*, asking what he thought to be an unusual test journal bearings and the result—phosphor bronze being the material employed. Some technical person who seems to know whereof he speaks and who writes over the initials "T. J." also of Pittsburgh, took the matter up, and after showing that the "tests" mentioned by the first were of the most common character, proceeds to give, in the same paper, an account of far better results from good brass bearings; giving the proportions of copper and tin composing the latter. The particulars with regard to both tests are given quite fully. "T. J." remarks that previous to reading the communication in relation to the tests with the phosphor bronze he was laboring under the impression that it was a superior composition for journal boxes and rolling mill brasses; but comparing the results of the two trials with similar work, his former opinion of phosphor bronze has been materially changed.

NEW POTTERY GLAZE.—M. Constantin, a chemist of Brest, has invented, for common pottery-ware, a glaze which is completely infusible, and which is destined to replace the glaze which, up to now, has been always

employed, and which has had the serious inconvenience of producing intoxications more or less mild. Already in 1872, M. Constantin had produced a glaze comparatively less dangerous by reason of the small quantity of lead which it contained. His mixture consisted of a silicate of soda added to powdered flint, with a very little minimum of red lead. Since that the glazes accepted at the manufactory of Lantilis, near Brest, do not contain any trace of lead. The two formulas which they use are: First, 100 parts of silicate of soda at 50 degrees; 15 parts of powdered quartz; 15 parts of Mendon chalk; or, second, 100 parts of silicate of soda at 50 degrees; 15 parts powdered quartz; 15 parts Mendon chalk; 10 parts borax. The addition of borax makes the glaze more fusible and brilliant; it requires a less vivid fire than the first formula, and it can be colored green by copper and brown by manganese.

Improvements in Telegraphic Apparatus.

A number of telegraphic instruments have been for some time in operation upon the Government lines between the Capital and the War Department, constructed and arranged on a plan invented by Mr. Merritt Galley, of Rochester, New York. An important feature of this system arises from the fact that there is comparatively little expense, and but little change of instruments. A common telegraphic instrument arranged for single transmission, as per old Morse system, may be converted into a line for transmitting messages in both directions at the same time, with the ability to draw a copy of either or both messages at any or all way stations of the line. The line has been in operation with batteries over twenty-five per cent. out of the balance, and still a margin of over twenty per cent. remained for the adjustment of instruments. Preparations are being made to place Mr. Galley's invention not only on all the Department lines, but also on the Signal Service. The Atlantic and Pacific and the Western Union Telegraph companies, as well as others, are also looking into the merits of the invention, with a view to its adoption, should it prove in every way satisfactory.

The most ingenious and perhaps the most important instruments exhibited by the inventor, are those for automatic transmission, in which the objections urged against the automatic in common use seem to be obviated. The invention is emphatically automatic—a single operator with it not only preparing accumulating matter for transmission, but it will transmit any portion of the same to its proper destination, having perfect control of the entire work even over a number of lines, while sitting at a single instrument. He exhibits an instrument which requires no perforated message stub, but by means of peculiar but simple mechanism transmits message after message with the instrument, until such time as the line can be secured, when by a stroke of single key they are sent into the line complete.

Achievements by the Sand Blast.

There has recently been exhibited in London, a plate of glass about half an inch thick, which by the sand blast has been pierced through in about ten minutes, and also a large flat file, in which a slit about four inches long and three-eighths of an inch broad, had been cut, by the same means.

The fact seems to be abundantly demonstrated, that sand, driven by an air blast of the pressure of four inches of water, will completely grind or de-polish the surface of glass in ten seconds. If the glass be covered by a stencil of paper or lace, or by a design drawn in any tough elastic substance, such as half dried oil, paint or gum, a picture will be engraved on the surface. Photographic copies in hi-chromated gelatine, from delicate engravings, have been thus faithfully produced on glass.

In photographic pictures in gelatine, taken from nature, the lights and shadows produce films of gelatine of different degrees of thickness. Now, it is found that a carefully regulated sand blast will act upon the glass beneath these films more or less powerfully, in proportion to the thickness of the films, and the half-tones or gradations of light and shade are thus produced on the glass.

Then, too, if the sand blast be applied to a cake of resin, on which a picture has been produced by photography in gelatine, or drawn by hand in oil or gum, the bare parts of the surface may be cut away to any desired depth. The lines left in relief will be well supported, their base being broader than their top, and there being no under-cutting—as is apt to occur in etching on metal with acid—an electrotype from this matrix may be made, and can be printed from an ordinary press.

STEEL VS. IRON.—The *American Manufacturer and Iron World* says: For many purposes steel, or those products generally called steel, such as Bessemer, homogeneous, etc., is rapidly superseding iron, and in the manufacture of all grades of steel, the tendency is towards the employment of processes that will permit not only of a largely increased output, but of the production of much larger masses. The Bessemer process, as is well known, accomplishes both of these results, giving a low grade of steel, that is a steel low in carbon. The Siemens-Martin and the Pernot modification of it give much better grades than the Bessemer, and the latter in masses fully equal to the Bessemer. We do not expect that steel will ever supersede iron for all purposes, but it is evident that the possibilities of steel neither in its manufacture nor in its applications are as yet reached.

SCIENTIFIC PROGRESS.

Progress of Solar Chemistry.

Several important circumstances unite to give unusual interest to the solar eclipse to occur in April next. The progress of solar chemistry has brought investigators face to face with problems of universal reach and significance, for the solution of which the four minutes of observation will be more valuable than as many years of laboratory work. A new instrument, the siderostat, destined, it is thought, to effect a great revolution in astronomical observation, will immensely increase the efficiency of spectrum photography; and the conditions under which the eclipse will be visible promise better opportunities for the observation of totality than can be enjoyed again before the close of the current century, or, more precisely, April 16, 1893. In not one of the four total eclipses of the meantime—1878, 1882, 1886, 1897—or in that of 1900, will the duration of totality be so great, or the central line of the eclipse present stations so favorable for observation.

Between the eclipse of 1860—during which photography decided the long vexed question of the origin and place of the strange red prominences seen round the dark body of the moon at the moment that the sun's disk is covered—and the eclipse of 1868, the spectroscopic had revealed the approximate composition of the sun's atmosphere, taken as a whole. The great point to be determined in 1868 was not simply the place and shape of the prominences, but their material. The result is well known, namely, that they consisted of glowing gas, or a mixture of such gases, shot to immense heights through the solar atmosphere.

Almost simultaneously with this discovery, it was found that the prominences could be studied spectroscopically independently of eclipses; and observers were not long in finding out that, outside the bright round face of the sun, was an envelope of glowing hydrogen into which magnesium and sodium, and more rarely, iron and other heavy metals, were injected from below, in the form of a vapor. It was further ascertained that the gases and vapors were not all mixed up together, but that the slightest, such as hydrogen, magnesium, and sodium were generally at top; and that, as the others were shot up from time to time, the heavier were located, as a rule, lower down in the solar atmosphere. During the eclipse of 1869 it was established that an unknown gaseous element, lighter than hydrogen, existed above that gas heretofore supposed to be the lightest form of matter. Since 1871 the spectroscopic study of the sun's chromosphere has been carried out to great advantage by Professor Young, at a mountain elevation of 9,000 feet in which clear atmosphere the chromosphere appears more complicated than when examined in the denser atmosphere below. Extensive laboratory researches have been undertaken under these conditions for the elucidation of the various phenomena connected with the sun's chromosphere. The study of the sun has enabled astronomers to explain the various classes of stars by supposing that, as a star grows older and colder, the metaloids are enabled to exist lower down in the atmosphere, and thus to change the character of the spectra of stars bright and hot into that associated with those which are dim and possibly colder; until at last the metaloidal rain, so to speak, falling on the metals below, gives the material of a future crust.

Associated with these chemical questions are physical questions of the greatest interest, the solution of which will help to make clear the development of our Universe from nebulae to suns and worlds. How far the coming eclipse will further the inquiry remains to be seen. It is confidently expected that the result to be accomplished will be "the fruit and crown" of the work begun in 1860, and carried on with so much zeal by all civilized governments since that time.

The course of the central line of this eclipse is mainly a sea track, yet, in its passage from the Nicobar islands, in the Bay of Bengal, to Siam, it crosses several points that will afford good stations for observation. At Kaikul, in the island of Camorta, totality will continue four minutes, twenty-seven seconds. On Bentinck Island, the maximum duration of totality will be four minutes seventeen seconds; at Mergui, four minutes, six seconds; at Tennaserim, three minutes, fifty-seven seconds; near Bangkok, Siam, to which point astronomers have been invited by the King, the total eclipse will last three minutes, fifty-four seconds.—*Scientific American*.

RELATIVE EFFECT OF WHITE AND RED HOT IRONS ON FLESH TEXTURE.—Dr. J. S. Camden publishes in the *Medical Times and Gazette* information very important to surgeons who are not cognizant of the fact, that the application of a white-hot iron to the body is absolutely painless, while when only red-hot it is an extremely painful operation. When operating with a red-hot iron on men the screeching was fearful, while when the iron was white-hot a murmur was heard; and when he operated so upon a horse the animal seemed scarcely to be aware of what was being done. He proposes to use for actual cautery a large spirit blow-pipe.

Curious Facts About Sponges.

Recent investigations have shown this curious fact about sponges. No matter how long a sponge may have been used, no matter how long it may have been kept dry, its life is apparently restored when it is wet. The sponge being wet with warm water and being placed in a warm room, the extremities of the sponge, after a little while, appear to be alive, and reach out like so many snakes. The longer they are, the greater the motion. It was observed that wetting the sponge with salt water seemed to increase the motion. Nearly half of all the slender points seemed to come to life, but after they become dry the motion ceases.

All sorts of dust were put upon the sponge so that they should be under the same circumstances as the pores of the sponge, but nothing but the pores of the sponge appeared to be in motion. Under the instrument, the sponge has no longer the appearance of a sponge; it appears like caverns, rocks, etc. These moving parts, when caught with pliers, would pull out a portion of the sponge. When there is much water in the sponge, they seem to be satisfied, but it is as the sponge is drying gradually that they appear to have life. This fact was discovered with an instrument which magnified only 42 diameters.

WIND-DRIFT EROSION.—At the Hartford meeting of the American Association for the Advancement of Science, a paper was presented by G. K. Gilbert, upon "Erosion by Sand in the Western Territories," and an abstract of the same is already in type for the forthcoming volume of the Proceedings. One of the topics discussed was the degradation of desert plains by drifting sand—a degradation evinced by the peculiar worn surfaces of the pebbles which strew the plains. The hard pebbles exhibit a high polish; the softer parts of the heterogeneous are deeply scored; and pebbles of limestone are carved with an arabesque plexus of furrows. In a subsequent note to the *Journal of Science*, Mr. Gilbert states that these phenomena were briefly noted by Dr. J. S. Newberry in 1861, and his observation has been cited as the first on record. But it is a well known fact that the phenomena were earlier observed by Prof. W. P. Blake, who published descriptions in 1855. His description, which is more extended than Dr. Newberry's, touches the majority of the features, and to him belongs the credit of having first discovered and truly explained the facts.

INTERESTING INVESTIGATION.—M. Faivre has recently performed a series of experiments of the mulberry, hazel nut, and cherry laurel, which he considers go far to prove the fact that the substances which supply the food of plants have an ascending motion in the bark. For this purpose he made perfect or imperfect annular incisions through the bark or detached pieces of the bark, to which buds were attached, or removed entire cylinders of bark from the trunk. The result of the experiments was that the buds always continued to develop when the communication remained uninterrupted with the lower portion of the trunk; while when this communication was completely destroyed, the buds invariably withered away. If the bud was separated by a perfect annular incision, it withered the more slowly the greater its distance from the incision; and in these cases the starch disappeared entirely from the incision; and in these cases the starch disappears entirely from position so the wood above the incision between it and the bud. When entire cylinders of bark with buds on them were removed, the buds continued to develop, and even produce branches bearing leaves.

THE REPORT OF THE GEOLOGICAL SURVEY OF MISSOURI.—This volume, comprising 734 octavo pages, besides index and plates, is a worthy successor to the report of Prof. Pampelly. Like that report, it treats with special fullness of the resources of Missouri in useful minerals and cannot fail of a direct and immediate effect in advancing the development of the State. We take pleasure in presenting to our readers as full an account of its contents as our limited space will permit. The plates appended to the volume comprise about ninety lithographic illustrations, referring, almost without exception, to ore deposits and mining and metallurgical operations.

IMMENSE PHOTOGRAPHS.—There are now on exhibition in Paris says the *Revue Industrielle*, the two largest photographs which have been made since the introduction of the art. One of these photographs represents the principal bronzes—the *Départure*, by Rude—of the *Arc de Triomphe de l'Etoile*. Each of the prints facade of the new Opera, the other one of the measures four feet three inches in length and three feet four inches in height. They were obtained in one single piece, by well known processes, and with the aid of a large and specially constructed camera.

THE EVAPORATION OF METALS BY ELECTRICITY.—Mr. Hopkins describes an interesting experiment, which consists in passing a charge of electricity through a very fine thread of platinum, or other metallic foil, the thread being kept in place between slides of microscope glass. The effect of the heat from the electric discharge is to vaporize the metal, which is instantly condensed in a transparent layer upon the cold glass, which can then be studied by the microscope, and can be used in various ways to determine the character of the metal and the peculiarities of the discharge.

Mining Stocks.

The Mining Stock market continues dull, with few sales at low prices. There seems to be no animation in any particular stock, and the depression from last week's prices is quite marked. Of the Comstock situation the *Enterprise* says: "At the northern end of the Comstock, in the bonanza region, in addition to drifting, the have gone to boring ahead into the ore body with diamond drills. In this new style of mining the only trouble met with is the occasional clogging of the drills, caused, as is currently reported, by their coming in contact with nests of stephanite and pockets of pure silver in which the diamonds slip and therefore make but little headway—which is 'important, if true.' Both in the Ophir (on the 1700-foot level) and in the California (1500-foot level, cross-cut No. 3) these drifts are now traveling eastward by day and by night. The open drifts are all showing up as well as could be desired, and what with boring and what with drifting, the known dimensions of the great ore body are every day increasing. Never before has it looked so well for the Ophir, and in the California and Consolidated Virginia it is said that pure silver looks cheap, and their only present thirst is for gold. It is now considered quite probable that the big bonanza will be found to back down south into Best & Belcher, and that it may not stop then, but reach down into the Gould & Curry; while at the north end it bids fair to plow its nose into Mexican and some of the mines beyond. The present is indeed a season of great expectations, and it is hard to say what will be the metes and bounds of the great ore body when its dimensions shall have been fully developed. For miles to the northward, companies are going down in the track of the great lode in the expectation of finding bonanzas, as yet unknown and almost unsuspected. To the southward the same is being done, but in that direction shafts have already been sunk to considerable depths, and most powerful hoisting machinery is already in operation, by means of which still greater depths in every shaft will very shortly be attained.

The Seattle (W. T.) *Intelligencer* of the 3d instant says: "There was a report current on the street yesterday to the effect that the Seattle Coal Company had entered into a contract with the Central Pacific Railway Company to supply them with coal for a period of three years, to the extent of 5,000 tons per month, and that Captain Blair, the owner of a large number of vessels plying on this northern route, having secured the contract for its transportation, would immediately put his vessels on the route between there and San Francisco.

The two foundries and two planing mills in Santa Cruz are busy turning out machinery and doing work for the two railroads now being constructed into town.

HEADSTAMP wants an assayer. The only question is, can it pay for such a luxury? There are plenty of assayers, but they will not work where they get only about one job a week.

An average of 120 car loads of ore is shipped daily over the Virginia and Truckee railroad to different quartz mills.

MINING SHAREHOLDERS' DIRECTORY.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

MORGAN M. CO.—March 13. Location, Calaveras county. Capital stock, \$2,000,000. Directors—C. T. Botts, Wm. Irvine, Robert Irvine, H. D. Bacon and Thomas Brown.

LA COMPANIA MEXICANA.—March 13. Object to purchase quartz mills and silver. Process in Mexico. Capital stock, \$10,000,000. Trustees—J. O'Connor, Louis A. Garnett, W. S. Rosecrans, John P. Miller, Louis Sloss, Noble Hamilton, O. C. Miller.

PACIFIC HYDRAULIC POWER CO.—March 13. Object to manufacture and sell waterwheels and other hydraulic machinery. Capital stock, \$1,000,000, divided into 20,000 shares, of the par value of \$50 each. Directors—C. E. Allen, Joseph Moore, J. B. Ford, John Skae and Hall McAllister.

MOUNTAIN QUEEN MINING CO.—March 16. Location, State of Nevada. Directors, James Byrnes, Wm. H. Bell, W. H. Lawrence, J. B. Carrick, J. C. Maynard, J. P. Ames and Thos. Boyce. The capital stock, \$3,000,000, divided into 30,000 shares.

LIBERTY MILL AND M. CO.—March 16. Location, Nevada County, State of California. Directors, Louis Franconi, Owen P. Sutton, Fred. W. Hutchins, Cyrus W. Jones and Julius Gogoulin. Capital stock, \$1,800,000, divided into 18,000 shares.

LAST CHANCE M. CO.—March 16. Location, State of Nevada. Directors, James Byrnes, Wm. H. Bell, W. H. Lawrence, J.

part of it. It is impossible to tell of this time whether the company have struck a fine body of ore that is lasting or merely struck a chimney. There was shipped to the bay, from the Lava Bed, just below Oroville, during the month of February about \$60,000 worth of gold dust that had been taken out by the Chinese men, notwithstanding the high water of the previous month. At present several large companies are not at work, but over \$40,000 will be taken out this month.

CALAVERAS COUNTY.

RICH ROCK.—*Calaveras Chronicle*, March 13: Last week was inadvertently neglected to mention a recent good clean-up of the well known Foster quartz mine, near Jesus Maria. A few tons of rock, worked in an arrastra, yielded 335. The ore was taken from the surface, an open cut having been run on the lead. The ledge is from six to seven feet wide, all good quality of ore. With adequate milling facilities the Foster would take rank among our most productive mines.

BLASTS.—Several blasts have been fired lately in the Duryea and Veith hydraulic claims, with uniformly good results. "T" shaped drifts were run into the banks, powder properly placed and the drifts tightly tamped. Fuse connected with the powder extends to the mouth of the tunnel by means of which it is exploded. Blasting is becoming an important auxiliary in gravel mining where the ground is so hard as not to pipe easily.

EL DORADO COUNTY.

MINING DEVELOPMENTS.—*Mountain Democrat*, March 13: At the Mansfield mine, Kelsey township, J. L. Smith, Superintendent, a body of decomposed quartz sixteen feet wide was recently struck in the lower tunnel. A sample was sent to Rich, Hemme & Co., San Francisco, who made the following return: The sample is found to contain at the rate of \$90.00 per ton in silver and \$1507.32 in gold, less 1 percent of moisture, equaling a net total silver and gold of \$1374.13 per ton. It is considered safe to estimate a large proportion of this vein matter as good for fully \$200 per ton by ordinary milling process. There is very promise that the Mansfield is about to develop into a first-class mine.

INYO.—*From Darwin.*—*Inyo Independent*, March 8: T. May and V. A. Gregg, Esq., returned couple of days since from Darwin. They report times somewhat quiet, though building goes on rapidly in the town and the prospect generally is very cheerful. The gold mines in the Argus range were attracting considerable attention among the Darwinites. The tunnel on the Defiance or Beltran is in 75 ft., cutting through a third vein about like the others mentioned heretofore, but was being driven for still another known to lie further back. This would indicate that this body of ore will prove to be nearly or quite 100 ft. It was rumored that Reddy and Beatty had purchased Rennie's sixth interest, paying therefor the sum of \$20,000 cash. The story remains to be confirmed, but the probabilities are that is true.

MARIN COUNTY.

QUICKSILVER.—*Cor. San Rafael Herald*, March 11: Quite an excitement was created on Monday last, at Olema, in consequence of Mr. Evans (Mr. Howard's Superintendent) finding in some very rich specimens of cinnabar, which he said were obtained from a ledge at Point Reyes. Some had been tested in San Francisco, and assayed from 60 to 70 per cent. As some remarks were made about its extreme richness for surface rock, he said he had sunk a shaft ten feet where he had obtained it. As Mr. Evans is a gentleman of veracity it of course left no doubt in the minds of the people. A few days previously Mr. Frank Miller brought in some fine specimens of the Payne lode, taken from a shaft which is working about half a mile northwest of W. Payne's claim. Mr. Miller says about a year ago a hunter brought him some cinnabar which he sent to San Francisco, and it assayed 76 1/2 per cent. As he could never find the ledge we suppose it must have come from the vicinity where Mr. Evans found his. Many supposed that the paint used by the Indians on Indian bay, in an early day, was obtained from the cinnabar ledge which has recently been discovered on Point Reyes. We understand that S. W. Payne, the discoverer, is sinking shafts on his claim.

EVADA COUNTY.

PROVIDENCE.—*Nevada Transcript*, March 11: In the 620-ft level in the Providence mine, there has been a cross-cut run from the hanging wall a distance of 108 ft, and almost the entire distance through quartz. At intervals there are seams of clay in imitation of foot walls, but when cut through a body of ore is reached. A ledge a hundred and eight feet wide is immense; but that is not all there is in the Providence. The workmen have found, still further on, another ledge, running parallel with the main ledge, the width of which is not yet found. The best part of all is, the rock is looking first-rate. The sulphurets are better than any yet found in the mine.

MANZANITA.—The Manzanita mine continues to look splendidly. Large pieces of rock are found, and on breaking them in two they are usually filled with gold. The short supply of water will interfere considerably with the amount of gold that was expected to be taken out this season. A large portion of the ore which has been got ready to work, and is now to contain a great deal of gold will not be touched for want of water. If we should

get a good storm, enough to keep up the water supply, the yield of this mine will be enormous.

CINNABAR.—*Grass Valley Union*, March 11: We have received a small specimen of cinnabar from uncle Jimmy Nickerson's ledge, situated low down on Wolf creek, near Bear river. There can be no doubt about the ledge carrying quicksilver, and as it is a large ledge and easily mined the property ought to be a paying one. Work is now being prosecuted on the ledge and a goodly amount of paying ore is on the surface.

PROSPECT.—This mine continues to improve. Specimens of the quartz brought in yesterday show well in gold bearing sulphurets. Miners who have worked in the Eureka and Idaho mines pronounce the Prospect rock to be about of the same character as that found in the two first named. The Prospect owners seem to have as pretty a showing for a big property as has been developed in this district for a long time.

PROSPECTING.—*Foothill Tidings*, March 13: Prospecting is quietly going on in more places than those who sit on the corners and whistle dry goods boxes are aware of. Passing over Osborn hill the other day we saw new work done in several places, and some good looking quartz piled up ready for the mill.

MOONEY FLAT.—*Nevada Transcript*, March 11: The Blue Gravel mining company is still at work running their tunnel from Deer creek to their ground. It is now in 900 ft. They are working ten men and work three shifts so that work is progressing as rapidly as possible. They drive about 20 ft a month and expect at that rate to reach the desired point in about a year. The tunnel will open up for work about 400 acres of gravel. It will make Mooney Flat a lively camp when everything goes on running nicely. It is thought Smartsville will be eclipsed in brilliancy at that time. The Blue Point mine, at the latter place, cleaned up the other day, \$79,600 from a 29 days' run. Mr. O'Brien, who is connected with the Blue Gravel company at Mooney's Flat, is also running a mine below Smartsville, on which he has 25 men employed, and uses 1500 inches of water. Altogether the mining interests of that section look and are very promising.

PLACER COUNTY.

NEW DISCOVERIES.—*Placer Argus*, March 13th: Yesterday we were shown a specimen of iron ore taken out of a large bed lately discovered near town, but the exact locality we did not learn. Whether it exists in sufficient quantity and is of a proper quality to be utilized, we do not know.

Mr. A. H. Estill, of Lincoln, informs us that a large bed of superior iron ore has been lately discovered a few miles from that place, which it is the intention of the owners to work. Mr. Joseph Stoddard, of the Union Flouring Mills, is owner of one-half of the claim.

PLUMAS COUNTY.

MINING NOTES.—*Plumas National*, March 13th: We hear some good reports from several of the mines in this neighborhood. Loring & Leovitt have struck some first-rate paying ground in the old Quirk claims near Elizabeth town, and recently got as high as \$80 to the set of timbers, regular old-fashioned "lead" gold. Braden, Richards & Blake are making good wages in Emigrant Hill, and have good indications of something better. The O'Neil Brothers are getting some good prospects in coarse gold in their Newtown claim. Bell & Co. are also reported to be getting some pay in the Old Western claim, near Newtown, and we saw a nice specimen from their claim the other day. The Maxwell company have repaired their flume, damaged by the flood, and are piping again. Miller, Shaffer & Mnck will make the old Blackhawk claim a "pan" this spring, as usual. The Plumas ditch company will make money this spring, but will be likely to suffer with the balance of the mining interest in a short water season. The Hungarian company are still running their pipes steadily, with good results. Myers & Siler are running a tunnel at Dublin Jack, and we are informed that they have a certainty of good paying ground as soon as they get to gravel, which will only take a week or two. Gould is rushing the work in his Mill creek claim. Several companies are working on Spring Garden creek, but we have no reports from them. Many a fortune lies buried in the ravines and gulches near this valley, and a little labor is almost certain to be richly rewarded.

SONOMA.

MINING ITEMS.—*Russian River Flag*, March 11: The Mt. Jack-on furnace has been roasting good rock since the 25th ult., and will be kept running without stopping for want of ore.

The discovery of a body of very rich ore is reported in the Great Eastern.

Work is active on nearly all of the prominent mines in the Sausal region, and the developments are very encouraging.

The tunnel on the Sansal mine is now in 40 feet and being run at the rate of two feet a day. It is expected to tap the ledge after going 30 feet further, at a depth of about 90 feet. Rich cinnabar and black oxide ore were struck in a surface cut last week.

Work is being pushed night and day on the Albamora tunnels.

The Rocky Bar company are running a large tunnel to tap the ledge 150 or 200 feet deep.

The Excelsior furnace is running satisfactorily, and rich developments have been made in both the Chapman and Maracoma.

SAN MATEO.

SILVER DISCOVERY.—*San Mateo Times*, Mar.

13: There has been, at various times in the history of this county, reports of mineral discoveries made in the shape of iron, coal, and quicksilver, and now we are called upon to add another to the list, which, if it turns out as is expected by the discoverer, will place San Mateo in the ranks of silver-producing districts. But a short time since Mr. Nicholas Larco, who resides on a ranch leased from the owners, who are residents of San Francisco, and which is situated about a mile and a half east of Searsville, became impressed with the idea that certain croppings which were on his place, and very near to the line of his neighbor, Dennis Martin's ranch, were nothing more or less than silver quartz. This proved to be the case. It would seem from developments since made that the result of Mr. Larco and his mining expert's investigation was that an immense silver ledge was on the lands, principally on the Mertin ranch, and that the dip of the lode was toward the latter, and that Mr. Larco had taken to San Francisco some specimens and had them assayed, the amount returned being \$420 to the ton.

SIERRA.

ORO STOCK.—*Mountain Messenger*, March 13: Stockholders of the Oro have decided to go to work and build a mill to reduce rock from their mine. The plans and specifications are all drawn, but it has not yet been decided whether to make it ten, fifteen, or twenty-stamp. The mill will be run by water, which will never fail. It is said by those who worked the mine when first opened, that the rock will pay from ten to fifteen dollars per ton. If we build this mill and it proves a paying investment, it will not be long before means will be found to put up a mill on the Good Hope, the rock from which has never paid less than \$12 per ton. There is, also, a strong probability that a mill will soon be put up on the ledges owned by Sam Hartley & Co., at the Clements bridge. With three mills running and paying, our town would be about as good as anybody's.

It is the present intention of the Oro company to commence work upon their mill immediately, and to have it in running order by the first of August.

TUOLUMNE.

NONPAREIL MINE.—*Union Democrat*, March 13: The persistent energy and perseverance of Jos. J. Du Prat and associates for the past three years in prosecuting work in this mine, situated at Deer Flat, promises to be finely rewarded. Saturday, the 6th inst., very rich quartz was struck in the east rise, the lode being 24 inches in width. Several years ago the work was carried on to quite an extent from the surface of the vein which yielded rich ore; as it was followed down the expense of working and keeping the mine free of water became too great, and operations were discontinued for a considerable period. It is gratifying to know that the great expense and time employed in developing this mine has not been lost. But few men or companies would, under the doubtful prospect, continued so long.

THE CUMMINGS MINE.—*Tuolumne Independent*, March 13: Near Yankee Hill, is now being opened by Cummings & Clark, for San Francisco parties. They have struck some very good rock near the surface, and the prospects are that they will develop a valuable mine. The vein at Rock Gulch was known to exist years ago, but like a good many other things in this county, it has laid idle all these years waiting for some outside party to come in and show us the wealth we are tambling over every day.

SOUTSBY MINE.—On the rise back of No. 6 south, south shaft, the vein is being met with which looks very promising, and will go from \$30 to \$40 per ton. This is entirely new ground which has never been worked. In the level above, from the 5th up, they had a very rich chute which continues. Hopes are entertained for its downward tendency below it—above is good indication.

MORE ENCOURAGEMENT.—The Marks & Darrow quartz mining company, since starting the new hoisting shaft No. 6, the depth of which will cut 350 ft of lode, about 25 ft more will, it is thought, cut through the main ledge. It is impossible to say how wide the quartz will be; but the superintendent thinks that it cannot be less than from ten to fifteen feet. In testing with a small force of men, about 200 ft north of the main shaft they have found very rich croppings, which the Dep't Sup't intends reaching by drift and stops from the main shaft. The rock from that portion of the lode (all of 300 ft from first level of main shaft to the surface), assays from \$1,700 to \$1,900 per ton, together with rock shipped from the main ledge, when reduced by mill process, produced by amalgamation alone, at the rate of \$1,900 per ton.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News*, March 11: Daily yield 450 tons of ore, keeping the mills of the company all steadily running. The ore breasts and stopes on the 1300, 1400 and 1500-ft levels never were looking better than at the present. Enlarging the main north and south drifts on the 1500 and 1600-ft levels to increase the air circulation in those portions of the mine goes steadily on, steadily increasing day by day the facilities for extracting the rich chambers of ore already developed, and prepare for the further development of the great bonanza in a downward direction.

OPHR. Daily yield 150 tons of ore. The ore breasts throughout the 1300 and 1465-ft levels are all looking splendidly, and yielding

the usual amount of good ore. Work is progressing finely in all the cross-cuts and drifts on both the 1465, 1500, 1600 and 1700-ft levels, with but little change in any portion of the mine during the week.

GLOBE CONSOLIDATED.—Since our last regular weekly report the main west drift has run into a ledge 1,124 ft west of the shaft, and today is into the same 18 ft. It is a ledge of very fine and valuable character, being evidently the same as that of the Rock Island. It gives assay thus far of from \$25 to \$60 to the ton, and is a very important development.

BELCHER.—Daily yield, about 450 tons, of fair milling ore from the various prospecting levels. The three winzes below the 1400-ft level are still in ore. The south winze is down 95 ft, the middle winze 81 ft, and the north winze 85 ft. The east drift from the main incline, to open on the 1500-ft level, is now in 262 ft, and is running in vein matter. The new air shaft is down 62 ft below the 850-ft level, and making very good downward progress.

BEST AND BELCHER.—Driving the south drift at the bottom of the winze at the 1700-ft level to connect with the main north drift from the Gould & Curry shaft on that level, is making good progress.

CALIFORNIA.—Sinking the C. & C. shaft is making excellent progress, the rock in the bottom blasting out finely. The north drift, on the 1550-ft level, is still driven ahead, the face in rich ore. This drift has been advanced 12 ft during the week. The north drift, on the 1500-ft level from cross-cut No. 1 east, has been connected with east cross-cut No. 2, and is now being continued north to connect with east cross-cut No. 3, to add still further to the ventilation of that portion of the mine. The ore in the face of cross-cut No. 3, on this level, still continues of a good quality. East cross-cut No. 4 is also in fair milling ore, and is being rapidly driven ahead. The south drift from the south winze, in cross-cut No. 2, on the 1400-ft level, is advancing rapidly toward the south line, the face still in good ore. This drift is now in a distance of 56 ft. The south winze, on the 1400-ft level, is still steadily advancing downward to connect with the 1500-ft level, the bottom still in ore of a fine quality.

LADY BRYAN.—The main west drift at the 380-ft level, is in 30 ft, with strong indications of soon reaching the main ledge. A small air shaft has been commenced on the surface nearly perpendicular over this body of ore, for the double purpose of prospecting the ore, which is supposed to extend nearly to the surface, and also to more thoroughly ventilate that portion of the mine.

MEXICAN.—The north drift on the 1465-ft level has shown little change during the past week in the quality of the material penetrated. Good headway is being made with the work. The pitch of the rich west body of ore recently struck at the 1600-ft station of the Ophir winze, to the north and east, is calculated to give great encouragement to the owners of the Mexican, as it is gradually increasing the surety of finding a continuation of the same body in the mine.

IMPERIAL-EMPIRE.—Sinking the main incline is making the usual good headway. The quartz in the face of the south drift on the 2000-ft level is looking more favorable for an ore development. No change of interest in the face of the east cross-cut on this level.

JACOB LITTLE CONSOLIDATED.—The main northwest drift shows great improvement as it advances further into the bill. Stringers or feeders of rich quartz are met with among the low grade ore passed through, and two or three tons per day of the best is saved and added to the pile already on the dump.

EUROPA.—The face of the east drift or cross-cut from the bottom of the winz, 115 feet below the adit level, shows more quartz and additional evidence of being close to the ledge. It is probably just cutting into it.

SOUTH COMSTOCK.—Sinking the main shaft progresses at the rate of two feet per day. Some little water is coming in, and, judging from the quartz seams and other indications, the ledge cannot be far distant.

JUSTICE.—Sinking the main incline is making excellent headway, there being no increase of water, and the new pumping and hoisting machinery working splendidly. The main drift south from the 800-foot station is now in 30 feet. This is a very important drift, as it will open the 800-ft level and pass directly beneath the very favorable ore developments made at the 400-ft level. Considerable water is coming in from the face of the drift, indicating a near approach to the vein.

UTAH.—Three car-loads of new pumping machinery, consisting of spur wheels, sole plates, engine beds, etc., were received at the depot of the Virginia and Truckee railroad, and will be placed in position ready for use at the mine at the earliest possible moment.

SIERRA NEVADA.—Sinking both the old and new shafts is making steady and rapid progress. The rock in the bottom of the new shaft blasts out finely, and the water no longer interferes in the least with the sinking. The bottom of the old shaft is in ledge material, carrying some low grade ore, but nothing yet that will pay the cost of extracting or milling.

LEO.—Making fine progress in driving the main tunnel ahead. Face of tunnel still in promising ledge matter. The ledge is large and well defined, and carries seams of ore of good quality.

WOONVILLE.—The ore stopes on the 300-ft level continue to yield the usual amount of good ore, keeping the mill steadily running. The ore developments in the east cross-cut, on the 300-ft level are looking more encouraging.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Seventh Lecture Delivered before the University of California College of Agriculture, on Wednesday, January 27th, by PROF. C. E. BESSEY.

The Walnut and the Nettle Families. Ingrandaceae and Urticaceae.

We take up two families to-day. First, the walnut family, *Ingrandaceae*—principal genus, *Inglans*—very nearly allied to the oak, is represented by only 30 species, mostly natives of North America. They are valuable for their timber and for their fruits.

Inglans Regia, the so-called English walnut, is a native of the Himalayan portion of Asia. It has long been under cultivation, and it is probably due to this fact that its shell is so thin and so easily broken. It has been introduced in California. Its wood is used for cabinet work in Europe. Its fruits are eaten, and are largely imported to the United States. From them a valuable oil is made.

The black walnut, *Inglans nigra*, of the United States, is one of the largest trees growing east of the Rocky mountain district, and grows to a diameter of six to ten feet. It is

One of the Most Valuable Trees

For its lumber, which is largely used for cabinet work and inside finish. Its fruits, being thick-shelled and rank, are not largely used as food. In Southern California some black walnuts which are native here, and which are a little different from the *I. nigra*, are grown successfully.

The white hickory, *Carya Alba*, called in the East shell or shag bark, white or Ohio bark, is a very large tree of the Eastern U. S., attaining a size of three to four feet in diameter and one hundred feet in height; yield a very valuable timber, which is very heavy, compact, and exceedingly tough, and which is used in ax handles, in wheels, and other parts of carriages. Though suited well for use where strength in a compact form is required, when protected by paint, it is liable when not thus protected to be affected by the powder-post insect, and is therefore not used in buildings. This tree produces delicious nuts.

Several nuts are fruits of an allied species, *Carya oliviformis*, which might be grown here. There is used the wood. Ash, which is largely used in the East, might be grown here.

We should try to import the Eastern live oak, and the European oak with its hard wood, and should make careful examination of our woods, such as we have, as to strength of material.

It would also be well to have a collection of woods. Each species should be represented by a cross-section as large as possible to show the character of the bark as well as the wood, also there should be a board as wide as possible, running to the bark, and specimens of fruit, leaves, cones, etc.

The Nettle Family.

Urticaceae. A large family of nearly 1,000 species, of diverse habits and botanical characteristics, lightly held together, but still existing, as four well marked sub-orders.

Sub-order 1. The stims. These are trees or shrubs, and are natives of temperate climates in the northern hemisphere. There are somewhere from 60 to 100 species; many of which are somewhat valued for their wood, it being used in some cases to fill out.

The common elm of Europe, *Ulmus campestris*, is largely grown here for its timber, which is especially valuable for underground use, or for use under water, as in making tile drains. Must either be very dry or wet to last well. It is sometimes grown in the United States as a curiosity or for ornament, and could be grown here.

The American elm, *Ulmus Americana*, is one of the most graceful of all the trees of the eastern forests. Its wood is valuable and is used for many purposes. Its toughness depends on where it is grown. It is not good for fuel, and it inclines to warp when it dries. It extends nearly to the Rocky mountains. There is none found native here. It is highly esteemed for its beauty. An allied species, *U. fulva*, produces the mucilaginous bark known as slippery elm bark, used somewhat in medicine. Hack berries, etc., belong to this order.

Sub-order 2. The bread-fruits and figs, trees or shrubs with a milky juice found in or near the tropics. Upwards of 250 species are known. There are no native species here.

Bread-fruit is produced upon a tree known to botanists as *Artocarpus incisa*. It is a native of many of the islands of the Pacific. It grows to the size of a large apple tree. The fruit is very much like the fruit of the straw berry; that is, an enlarged, spongy receptacle

bearing little nuts. The whole mass is about a foot long and is in shape not unlike a melon. [Fig. 1.] These fruits are gathered before they are ripe, roasted and eaten by the natives, and are quite palatable.

In 1793, they were introduced into the West Indies, and now they are grown in nearly all the tropical countries.

The cow tree, *Galactodendron utile*, is a native of Venezuela. It grows to the height of 80 to 100 feet, and forms large forests. Upon incisions being made it exudes a quantity of whitish fluid, which has a pleasant taste, and which is used as a substitute for milk.

The fig, *Ficus carica*, is a native of Western Asia, but it is now grown throughout all warmer regions of the globe. Its fruit is peculiar. It is of considerable interest in this State and no doubt will become more important.

The mulberry, *Morus nigra*, is a native of Western Asia, grown largely in Europe and parts of the United States for its fruit. It is a near relative of the fig.

Ficus elastica, the India rubber tree of Southern Asia, produces the material from which its name is derived; its milky juice being evaporated for this purpose. It has thick, broad, tough leaves. [Fig. 2.] This, however, is not the tree from which most of our India rubber is obtained.

[Allusion to which is made elsewhere in the course of lectures.] This white mulberry, *Morus alba*, is extensively used for feeding silkworms.

Osage oranges, *Machura aurantiaca*, is used very largely for a hedge plant. On account of its strong spines and rigid branches, it is especially adapted for this use. It is a native of Arkansas, Louisiana, Texas and other southern localities.

Among the remarkable trees of this sub-order are the upas tree, *Antiaris toxicaria*, a poison-

Fig. 11.

Compound Leaf of India Rubber Tree.

one trees of Java, and the banyan tree, *Ficus Indica*, of India.

The banyan has root-like branches and one tree may spread over

Five to Eight Acres.

This paper mulberry, *Broussonetia papyrifera*, of China, Japan, and the islands of the Pacific, grows from 20 to 30 feet in height. Its bark, which is filled with long fibers, is made into paper and cloth. It is cultivated also as an ornamental tree.

Sub-Order 3—The Nettles.

These are herbs, shrubs, or trees and number about 300 species, found in the temperate or warmer climates. The genus *Urtica* includes the many species of nettles, which occur as weeds in temperate climates and as trees in the tropics. All are possessed of stinging bristles which are bad enough in the small species found in our latitude, but which are hardly to be compared to those occurring in India and Australia. One species, *Urtica gigas*, found in the latter country, grows to be a tall tree 70 to 80 feet high, and its sting is so severe as to even threaten death. Cattle coming in contact with its leaves become

Furious With Pain.

Ramie, or the grass cloth plant, *Boehmeria nivea*, is a perennial herb; a native of China. It is coming into cultivation for its fiber, which is made into a fine, linen-like cloth. It is cultivated in the Southern U. S. and in India.

Sub-order 4—The Hemp and Hop.

There are two species. Hemp, *Cannabis sativa*, is a native of northern India. It is grown in the U. S. for its fiber, and in parts of India for smoking. It possesses narcotic properties lying between tobacco and opium. From the dried plant are obtained what are in India known as *gunjah* and *bang*. The first is smoked; the latter, made into an intoxicating drink. The virtues of *gunjah* and *bang* are concentrated in the resinous matter found on the stems and leaves. It is highly intoxicating, and servants sometimes obtain it by running

through the field, allowing their clothes to come in contact with it, and afterwards scraping off the adhering substances. The seeds are sometimes fed to birds for the purpose of rendering them drowsy enough to be caught.

The hop, *Humulus lupulus*, is grown in all countries. In its strobili it has a secretion, and in this its virtue, which renders it desirable in the manufacture of beer.

Devil's Gate Reviving.

Any one who visits Silver City for the first time will see everywhere about him indications of an old-settled country. Many of the locust trees are six or eight inches in diameter, and were planted at least twelve years ago. The remains of stone cabins are visible, where the miners in the early days of Washoe cooked their bacon and made saleratus bread, while visions of wealth, before which the wondrous yield of the Gould & Curry passed, floated through their excited imaginations. There are the ruins of old primitive quartz mills and arrastras, which have been long since abandoned, as the rich croppings on the surface ran into barren quartz. The stream flowing down Gold Canyon, which was one of crystal purity, is now turbid with tailings and the refuse of reduction works at Gold Hill. The ancient prestige of Devil's Gate has long since faded, and of the hundreds of prospectors who sunk shafts and ran tunnels, the mouths of which lined the road on both sides, scarcely one is left. But the region has not been abandoned by any means. On the contrary, its promise is more flattering than was ever anticipated by the most sanguine of the original miners. The Justice, Woodville, New York, Lady Washington, and other well-known mining companies, are sinking shafts hundreds of feet in depth, and have a fair prospect of striking the rich ore of the genuine Comstock. Within the last two years the lower end of the vein has commenced a new era of progress. Costly hoisting-works, supplied with new and improved machinery, are being erected, and many mining experts are of the opinion that developments will be made equal in extent and richness to the best mines further north on the ledge. Silver City itself sympathizes with this mining improve-

Fig. 1.

Fruit and Leaf of Bread Fruit Tree.

ments in its vicinity, and is improving with astonishing rapidity. On the hills on the east side of town a great number of elegant and substantial dwellings were erected last season, and the number will be doubled during the coming summer. Real estate is held at a high figure, and, from present appearance, it will not be long before a continuous city extends from below Silver City on the south to Cedar Hill on the north.—*Virginia Enterprise*.

THE GOLD HILL CHASM.—Although Gold Hill may have no big bonanza just at present about which to brag, she can boast the most extensive crack in the country. This crack, fissure or chasm made its appearance on the surface of the ground to the eastward of Fort Homestead over a year ago, since which time it has gradually been increasing in size. At present it is about three-quarters of a mile in length and two and three feet in width in places. The site of the town of Gold Hill has been undermined by the various companies who have for years been engaged in working that portion of the Comstock, and the underground workings have ever been carried under the base of the hill on which stands Fort Homestead. This hill stands just east of Main street, and it appears—by the chasm which has opened behind it—to be gradually settling. As the ground which has been worked out is not only timbered, but is also everywhere filled in with waste rock, there appears to be no danger of anything more than a gradual settling. As the big crevice has not followed ravines and other natural depressions, but holds a straight course across hills and hollows alike, it is evident that the break must be through a weak place in the underlying rock; and as this weak streak can be nothing else than a large clay seam, there can be no doubt the opening is along a portion of the east clay wall of the Comstock lode. We suggested that at the time the crevice first made its appear-

ances and also called attention to the fact that along the line of the crack the sagebrush and other shrubs grew to about twice the height of those on either side, showing that the ground underneath was both softer and more moist than in other places, as it naturally would be where a large seam of clay came to the surface. The difference in the growth of the vegetation was so great that it could be seen at the distance of half a mile, and the course of the crevice could be traced, when it could not be seen, by the long line of tall bushes. We at that time recommended prospecting on the line of this break in the ground. Nothing was then done, but several companies have now fallen into this along this fissure, and are sinking shafts upon it. They will undoubtedly find the true east wall of the Comstock, and may make some discovery of great value.—*Virginia Enterprise*.

The American Patent System.

The Society of Arts, in England, has been discussing a paper proposing the abolition of the patent system; and the debate wandered into a desultory comparison of the codes of the different countries. Mr. H. D. Wood distinguished himself by an attack on the American system, which may have seemed plausible to his auditors, but which certainly displays considerable ignorance of the subject. The cardinal differences between the English and American practices seem to have been quietly ignored. In this country an attempt is made by the Patent Office to inquire into the novelty of an invention; and this inquiry, though it may not be absolutely conclusive, is at least as thorough as the inventor could make for himself. The fees he pays purchase for him, therefore, the advice of an expert; and when he goes into court, if necessary to sustain his claims, he is backed by the moral force of the verdict already rendered in his favor by the examiner. For much less money than the English applicant is forced to pay he gets much greater value. An English patent has no greater force than the announcement of an invention in a newspaper. It carries no presumption with it, in favor of the patentee. Mr. Wood mentioned a number of specifications issued at Washington, which he regarded as trivial and useless. They included, according to the published report of his remarks, the opening of an envelope by means of a thread affixed thereto, a method of fixing a small mirror to a toilet-glass to enable a lady to see her back hair, a method of cutting boot soles, the packing of ground hops in air-tight cases, and the making of shovels of cast iron. Assuming that each of these was novel, we do not see why they should be branded as useless. The object of a patent is to make it the interest of somebody to introduce a new device. If it is useful enough to make people buy it, then the granting of the patent is certainly justified. If not, then what harm has been done?

It is true that the overworked and underpaid examiners of our Patent Office are not always thorough and intelligent enough in their inquiries, and that even the remedy of appeal to the Commissioner does not make this working of our system perfect. There is room also for an honest and consistent opposition to any patent system whatever, and a preference for some other reward, or no reward at all to the inventor. But what we claim is, that if a patent system is to be maintained, the American is by far the best, inasmuch as it makes the burden upon the applicant as light as possible and gives him as much as possible for his money.—*Exchange*.

Glove Manufactory.

There are quite a number of glove manufacturers in various parts of this State. There are several in this city to which we propose to make particular reference in future numbers. There is an establishment of this kind in Napa, in which an average of seventy-five deer and fifty sheep skins are daily converted into glove material. The process of tanning employed there says the *Napa Register*, is a secret. It is essentially a chemical process of which the public know nothing, except its beautiful results.

An article of sheep glove leather is made of hers of wonderful strength and exquisite finish. It is really beautiful. It is made of various styles and colors to suit the public taste. Deer skins are also finished up in variety of styles to suit the market. The weekly product of glove leather averages 75 skins. The raw material is purchased at a points in the interior and along the coast from the Columbia river to the Mexican boundary. The purchases are generally direct, and not through Commission houses. Here may be seen piled up by hundreds, or perhaps thousands, deer skins in all stages of manufacture.

In addition to the above about 9,000 sheep pelts are tanned and made into ordinary leather monthly. They yield about 20,000 pounds of wool. Wool washing is also carried on extensively, and for two or three months in the year, from 2,000 to 3,000 pounds of wool per day are cleaned and graded. There are many localities in the State where this branch of business might be profitably introduced.

THE SPRINGING OF SHAFTS.—If a shaft spring in running, the trouble lies probably in either too small diameter of the shaft for its weight and velocity, a set of unbalanced pulleys, or unequal strain on either side by the belts.

USEFUL INFORMATION.

Physiology of Eggs.

Every fowl has two small organs near the extremity of the body called the ovaria. They are filled with elastic tissue, and feel under the finger like a sponge. The eggs are started here, and those which will mature a year or two, or three years hence, are in embryo. One is forced up, is sized by the stroma, which is seventeen inches long and passed rapidly through. When the egg leaves the ovary it consists of yolk only, but in its passage through that short canal the yolk is surrounded by enough albumen to perfect the chick. The white of the egg has in it all that nature requires for making bones, muscles, blood vessels, connecting tissues, skin and feathers.

Just before the egg leaves the body, this canal has the power of secreting lime for the shell. This shows how valuable the egg is as nutriment, and also what demands are made for rich food by a hen that lays an egg daily. Besides what she requires for her sustenance, she is called upon to secrete the material for the body of an entire chick, and also retains for the little creature sufficient to last many hours after it leaves the shell. It shows also that a hen cannot make albumen so rapidly except out of albuminous food, such as wheat, meat and small animals.

It is not true that there are a certain number of eggs, and that this number exhausted, no more can be expected; but it is true that the secretions lessen as old age comes on, and latterly the hen fails to have sufficient force to carry forward the process. The practical bearing of this is that we must see that the fowl is always well kept. The way to have good laying pullets is to quicken the circulation and strengthen the system by liberal nutriment. The yolk is food for the first three or four days. Careful housewives make a mistake by attempting to feed them before the expiration of this time. Let the mother bird have charge and success will be certain, for she knows better than any man can what the chick requires.—*Poultry Review.*

A NEW PREVENTIVE FOR THE EFFECTS OF BEE-STINGS.—Mr. G. Walker has made some interesting (but unpleasant) experiments lately, whereby he has proved that immunity from the pain and other effects of the stings of bees can be obtained by inoculation. The following description of his manner of experimenting on himself is taken from the *Lancet*:

He went to one of his hives, caught a bee, placed it on his wrist, and allowed it to sting him, taking care that he received the largest amount of poison by preventing it from going away at once. The first few stings he got during this experiment had the usual effect; the whole of his forearm was affected with a cutaneous erysipelas, and there was disorder of the nerves, accompanied with heat, redness, swelling and pain. This attack lasted till Tuesday, and on Wednesday, October 7th, he was so far recovered that, following the same plan, he stung himself three times more, also on the wrist. The attack of erysipelas this time was not nearly so severe, but, as before, he felt a stinging sensation as far up as his shoulder, and he noticed that a lymphatic gland behind his ear had increased considerably in size, the poison having been taken up by the lymphatic system. On Saturday, October 10th, he again treated himself to three stings, and the pain was considerably less, though the swelling was still extensive. At the end of the next week (October 17th) he had eighteen stings; then he stung himself seven times more during the next week and reached the number of thirty-two on October 31st, the course of the experiment having lasted nearly four weeks. After the twentieth sting there was very little swelling or pain, only a slight itching sensation, with a small amount of inflammation in the immediate neighborhood of the part stung, which did not spread further.

MODE OF ASCERTAINING THE VARIOUS KINDS OF MATERIALS IN MIXED FABRICS.—A German industrial journal gives, after M. Vupp, the following treatment for fabrics containing silk and wool, with vegetable fibers. All vegetable fibers resist caustic alkaline solutions, even when boiling, and are dissolved by sulphuric, nitric, hydrochloric acids, even when diluted with odor. Vegetable fibers when burnt do not give forth any characteristic odor. Wool, insoluble in the above acids, is readily attacked by caustic alkalies, especially when hot; the sulphur which it contains combines with the alkali, and the solution becomes black when acetate of lead is added to it. In burning, wool produces the same smell as horn. Silk is dissolved both in the acids and the caustic alkalies, and produces an odor similar to that of wool, but it contains no sulphur, and, consequently, its solution in alkalis is not blackened by acetate of lead. In order to distinguish these materials in a tissue, it is treated first with concentrated hydrochloric acid, cold; the residue is then washed in a filter, and, if necessary, bleached, by means of water containing chlorine, and then washed again in pure water and boiled with caustic soda, which dissolves the wool, leaving the vegetable fiber intact. The wool is distinguished from silk by adding acetate of lead to the liquid, as already mentioned.

A DESTRUCTIVE WORM.—It is estimated that the army worm destroys \$50,000,000 worth of cotton annually in the Southern States.

Effects of Poisons on Molluscs.

Professor William North Rice, of Middletown, Conn., states that among the most interesting results of his experiments was the observation that certain poisons, which set with extreme violence upon the mammalia, are very feeble in their action on molluscs. This is especially true of hydrocyanic acid and woorara. Specimens of *Ulyanassa obsoleta*, immersed in dilute hydrocyanic acid on Friday, showed somewhat feeble signs of life on the following Tuesday. A specimen of *Lunatic heros*, into which a quantity of woorara had been injected, was found the next day to show no sign of any injury. Indeed, both of these poisons seemed to produce death very little sooner than the animals would have died in stale water. The sudden introduction of a large amount of carbolic acid in the manner which has been described, seemed to produce no decided effect. On the other hand, chloral hydrate seems to be very suddenly fatal, the animals treated with it becoming justly contracted, and not resuming their activity when kept for a number of hours in sea water. Cyanide of potassium is similar in its effects, though not quite so instantaneously fatal. The effects of quinine are similar, though less energetic. Chloroform produces instantaneous contraction, and probably death.

WATERED BUTTER.—In the course of some investigations made by Professors Agell and Hehner, England, out of analyses of fifteen samples of butter which were determined by them, twelve of the samples, which were undoubtedly good butter, contained 6 to 13 per cent. of water; the astonishing quantity of 42.3 per cent. was found in one sample from London, or an excess of about 32 per cent. of water, for which Londoners pay from 32 to 48 cents per pound. Another butter from the same place had 24 per cent., these high ratios being due to the fact that the butter had been treated with milk. On the other hand, a sample purchased in Ventnor was found to contain under 4 per cent. of water, and according to the author it contained 50 per cent. of foreign fat. The authors also found that genuine butter spread out on a sheet of paper and exposed for a week to the air in the laboratory became, so far as the senses could judge, indistinguishable from tallow.

GOOD HEALTH.

Don't Worry About Yourself.

To retain or recover health, persons should be relieved from anxiety concerning disease. The mind has power over the body. For a person to think he has a disease, will often produce that disease. This we see effected when the mind is intensely concentrated upon the disease of another. It is found in the hospitals that surgeons and physicians who make a specialty of certain diseases are liable to die of them themselves; and the mental power is so great that sometimes people die of diseases which they have only in imagination. We have seen a person seise in anticipation of a voyage, before reaching the vessel. We have known a person to die of cancer in the stomach, when they had no cancer or any other mortal disease. A blindfold man, slightly pricked in the arm, has fainted and died from believing that he was bleeding to death. Therefore, well persons, to remain well, should be cheerful and happy; and sick persons should have their attention directed as much as possible from themselves. It is by their faith that men are saved; and it is by their faith they die. As a man thinketh so is he. If he wills not to die, he can often live in spite of disease; and if he has little or no attachment to life, he will slip away as easily as a child will fall asleep. Men live by their souls and not by their bodies. Their bodies have no life of themselves; they are only receptacles of life—tenements for their souls, and the will has much to do in continuing the physical occupancy or giving it up.

The increased longevity of latter times is less owing to improved therapeutics than improved hygiene. Dr. Lion Playfair says in a late paper read at Glasgow: When the Egyptian, Greek and Roman civilizations expired with their baths and divine maxima about ablutions and purifications, dirt reigned for a thousand years. Not a man or woman in Europe ever took a bath; hence the spotted plagues, the black deaths, the sweating sickness, the dancing manias, the mewing manias, and biting manias that ravaged the people and cut off in the middle ages, one-fourth of the entire population. Religion came to the aid of dirt; the more filthy a saint was the more saintly he was considered. Some of the hermits never changed their cloths, and only combed their hair once a year. St. Anthony never washed his feet, and St. Thomas a Becket's undergarments acquired an additional sanctity from the vermin they contained. Nervous diseases, the result of superstition, were frequent, and often attributed to demons.

SHOCK OF RAILWAY ACCIDENTS.—Shocks in railway accidents require to be treated with perfect rest and sleep. We have known the effects of a shock to last a whole year. Many lives are lost at railroad accidents for want of perfect quiet and rest for days, often weeks. If a bone is fractured, when the car run off the track and the train is broken to pieces, it is palpable to the senses; but injury to the nervous system may be more severe, and no eye can detect it, and the patient thinks it right when it is a positive injury to the nervous system.

Insulated Beds.

An insulated bed is one set on some non-conductor of electricity, so the electricity cannot flow to and from it freely. Their usefulness is as yet a matter of experiment. Their value might be tested by invalids, at little expense, for an insulated bed can be made by placing the four feet on four strong glass tumbler. Dr. Wagenhols, of Columbus, Ohio, recently read an article on the subject before a medical society, detailing many cases of acute rheumatism which had been benefited by sleeping on an insulated bed. We quote:

"On December 25th, 1871, I was attacked with rheumatism of the ankle and knee joints in one limb, then the other. I treated myself actively by alkalies, opiates, etc., in the ordinary manner recognized by the profession as of almost value in this disease. I was unable to leave my bed for three months, could not walk until April, 1872, and did not fully recover until the warm weather in June. On the 16th day of December I was again assailed by my tormentor, treated myself as before, and I thought myself happy that I was able to be out of my room in eight weeks, privileged to hobble around the streets of the city with the aid of a cane. Warm weather restored me to health, and during the summer and winter I attended to my professional duties. On February 16th, 1874, while I was congratulating myself that I should escape my annual attack, I was suddenly seized in the night time with severe pain in both ankles. In the morning I failed, after an arduous effort, to leave my bed. Fever was intense, as also the swelling of ankle and knee joints. A sense of coldness of the lower extremities existed, which was even more distressing than the pain caused by the swelling of the joints. This condition continued until the morning of the 18th. From the 16th to the 18th I was unable to sleep. On the morning of the 18th I insulated my bed by causing the legs of the bedstead to be placed in four glass tumblers. I fell into a profound sleep, waking on the morning of the 19th bathed in a profuse perspiration, without the aid of anodynes. I steadily improved, and in a few days was out of my room.

"This single case is of little consequence, but the Doctor gives a large number of others corroborating it. How much is due to insulation and how much to the expectation of a cure, we cannot tell. As the remedy is perfectly hygienic and easily tried, we hope further experiments will be made.

The closing part of Dr. Wagenhols' paper is suggestive, and we quote it:

"One of the patients makes mention of the sensation of drowsiness which came over him by the prolonged use of the insulated bed. This I have noticed in several cases, and distinctly observed it in my own. Now the question is, do the effects of this form of treatment, which in comparison with our former modes, is simply marvelous, depend upon expectant attention? Is it another specimen of the wonderful power the mind has over the body, or does it depend upon changing the electric state of the body? It certainly deserves attention, as, in either case the patient is benefited, and this is the end of all therapeutics.

"I have in my possession several communications from gentlemen of worth and eminence in the profession, who fully corroborate my experience in the particulars set forth; and I am confident that if this subject, which I deem important to the profession as well as to the community, is properly tried and thoroughly investigated, much information will be gained and large beneficial results will be accomplished.

"We live to learn; as we learn we advance in knowledge, our information and attainments expand, and thus our usefulness is made felt in communities in which we reside, and our vigor and energy is undaunted, by reason of the good results we obtain."—*Herald of Health.*

A Cure for Lockjaw.

In the course of lectures recently delivered before the British Society of Arts, by Dr. Benjamin Richardson, the following important remarks were made upon nitrate of amyl:

One of these specimens—I mean the nitrate of amyl, has within the last few years obtained a remarkable importance, owing to its extraordinary action upon the body. A distinguished chemist, Professor Guthrie, while distilling over nitrate of amyl from amyl alcohol, observed that the vapor when inhaled quickened his circulation and made him feel as if he had been run over. There was flushing of his face, rapid action of his heart, and breathlessness. In 1861-2 I made a careful and prolonged study of the action of this singular body, and discovered that it produced its effects by causing an extreme relaxation, first of the blood vessels and afterward of the muscular fibers of the body. To such an extent did this agent thus relax, I found it would overcome the tetanic spasm produced by strychnia; and having thus discovered its action, I ventured to propose its use for removing the spasm in some of the extreme spasmoid diseases. The results have more than realized my expectations. Under the influence of this agent, one of the most agonizing of known human maladies, called *angina pectoris*, has been brought under such control that the paroxysms have been regularly prevented; and in one instance at least altogether removed. Even tetanus, or lockjaw, has been subdued by it; and in two instances of an extreme kind, so effectively as to warrant the credit of what may be truly called a cure.

DOMESTIC ECONOMY.

LIVING TO EAT, AND EATING TO LIVE.—Eating is a necessity of life, but the spectacle presented at some tables when the family has assembled for a meal might well suggest the question, do these people know why they eat? To be sure no little knowledge is requisite if we would supply the wants of nature in the proper manner; but is there any hardship in informing one's self with respect to so important a matter as the preservation of a strong, healthy body? Is health, and its accessory ability to perform life's duties well, a minor consideration, quite inferior to a knowledge of arithmetic, or geography, or of the mechanics or music? An eminent English observer has said that "a man must live forty years before he knows how to eat." True enough according to the prevalent mode of gathering the knowledge of what is fit or unfit for our stomachs as we go along in life, thus making our system a sort of experimental laboratory for the analysis of all sorts of so-called pabulum. And how few survive forty years of constant experiments with their alimentary function.

The masses are yet quite ignorant of the philosophy of nutrition, and riot in their ignorance. The housewife may be skilled in the preparation of toothsome dishes, but very rarely knows what is suitable or unsuitable among her materials for the uses of the body. If the article "tastes good," that quality is generally a sufficient warrant for its appropriation.—*Annual of Phenology.*

THE modern kitchen is the cooks fortress; from it drawing-room company is carefully and jealously excluded. In all families the children look upon the kitchen as a paradise of dainty devices. In some they are never allowed to enter; but in others the little missy is sometimes privileged to make a bit of paste into ducks and drakes, or to knead some dough into a cake for the doll's birthday. Such frivolities a modern cook sternly represses. She supposes the young ladies will want to make puddings next or to come down and try recipes out of "them rubbishy books." She has no notion of encouraging such pranks. A favor has to be made of leave to use her bowls and spoons, and the young officer just home from his regiment dare not venture into the sacred precinct to concoct a real Indian curry or a Mulligatawny pillow unless he has first ascertained that cook is in a good humor. Even the lady of the house is informed very plainly that after her morning visit she is not expected to disturb the quiet of the lower regions.

HOW TO COOK OATMEAL.—First, be sure to get new, fresh oatmeal, as if it becomes damp or old it is bitter. Put one quart of water into a tinned stew pan, salt sufficient to be palatable; stir in carefully so as not to have it lumpy, three or four handfuls of oatmeal. Put it over the fire and stir continually until it has swollen all it will, using care not to have it burn on the bottom. When it has swollen all it will, add more water, and then put the stew pan into a kettle of hot water and leave it cooking for several hours—the longer the better, as the longer it is cooked the softer and more jelly-like it becomes. Having the stew pan in another kettle of hot water prevents its burning on the bottom, and you are relieved from constant stirring. It is good with milk, syrup or sweetened milk, or even with butter alone.

SOMETHING NEW IN THE PRESERVATION OF FRUIT.—The following method for the preservation of fruit has been patented in England. The fruit is placed into a vertical vessel in layers, separated by layers of pulverized white sugar, and is then covered with alcohol of 80 degrees Gay Lussac. After 12 hours the closed vessel is inverted and the maceration allowed to continue from 12 to 72 hours, according to the nature of the fruit, which is then removed and allowed to drain and dry. About two pounds of sugar and two pounds of alcohol are recommended for four pounds of fruit.

RAISED CONNECTICUT DOUGHNUTS.—Heat a pint of milk just lukewarm, and stir into a small cup of melted lard and sifted flour, till it is a thick batter, add a small cup of domestic yeast, and keep it warm till the batter is light, then work into it four beaten eggs, two cups of sugar rolled free from lumps, a teaspoonful of salt, and two of cinnamon. When the whole is well mixed, knead in wheat flour until as stiff as biscuit dough. Set where it will keep warm, till of spongy lightness, then roll the dough out half an inch thick, and cut into cakes. Let them remain till light, then fry them in hot lard.

CRUSTED APPLE PUDDING.—Pare, core and stew slightly, two quarts of tart mellow apples, and place them in a pudding dish; then, to one and a half pints of wheat meal, add one gill of Zante currants, and boiling water enough to make a dough, stirring lightly until mixed; roll it out one-third of an inch thick, and spread over the apples. Bake it in a quick oven forty or fifty minutes, take out, reverse on a hot plate, mash the apples with a spoon, and sweeten, if desired; cut it in pieces like a pie, and serve warm, with some fresh sauce.

SHAKESPEARE CAKE.—Six cups of flour; one of sugar; one of rich cream; eight eggs.

San Francisco:

Saturday Morning, March 20, 1875

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.—Hydraulic Mining in California—No. 17, 117.
Among the Foundries and Machine Shops; Coal as a Raw Material; Notices of Recent Patents, 184.
Terraces in the Coast Range; Academy of Sciences; A Rustic Shelter, 185.
ILLUSTRATIONS.—Hydraulic Mining in California—No. 17, 177. A Rustic Shelter, 185.
CORRESPONDENCE.—Mexican Mines, 178.
MECHANICAL PROGRESS.—New Uses for Copper; Mica Substitutes for Stoves; Brass vs. Phosphor Bronze Bearings for Rolling Mill Use; New Pottery Glaze; Improvements in Telegraphic Apparatus; Achievements by the Sand Blast; Steel vs. Iron, 179.
SCIENTIFIC PROGRESS.—Progress of Solar Chemistry; Relative Effect of White and Red Hot Irons on Flesh Texture; Curious Facts About Sponges; Wind-drift Erosion; Interesting Investigation; The Report of the Geological Survey of Missouri; Immense Photographs; The Evaporation of Metals by Electricity, 179.
MINING STOCK MARKET.—Thursday's sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 180.
MINING SUMMARY.—from the various counties in California and Nevada, 180-81.
POPULAR LECTURES.—Economy of the Vegetable Kingdom, 182.
USEFUL INFORMATION.—Physiology of Eggs; A New Preventive for the Effects of Bee-Stings; Mode of Ascertaining the Various Kinds of Materials in Mixed Fabrics; Effects of Poisons on Molluscs; Watered Butter, 183.
GOOD HEALTH.—Don't Worry About Yourself; Shock of Railway Accidents; Insulated Beds; A Cure for Lockjaw, 183.
DOMESTIC ECONOMY.—Living to Eat, and Eating to Live; How to Cook Oatmeal; Something New in the Preservation of Fruit; Raised Connecticut Doughnuts; Great Apple Pudding, 183.
MISCELLANEOUS.—Open Ore Market, 178. Devil's Gate Revolving; The Gold Hill Chasm; The American Patent System; Glove Manufactory; The Springing of Shafts, 182.

QUICKSILVER IN OREGON.—The Jacksonville Times says: The cinnabar deposits discovered in Sam's valley are reported to be exceedingly rich in the metal. This district is said to embrace about ten miles of country, several of which are already claimed. One of the locators claims that he does not exaggerate in the least when he says these mines will rival the New Almaden in point of abundance and richness. The rock is of a yellow cast, but when crushed exhibits a blood-red color, strongly impregnated with quicksilver. Some work has been done on these mines, and those interested are sanguine of having struck it rich.

THE "City of Peking" reached Yokohama on the 13th inst., making the voyage from this port in 20 days, two days less than the schedule time. She lost a propeller arm on the voyage. It will be remembered that she lost three arms on the voyage from New York to San Francisco. The "City of Tokio" also lost an arm of her propeller on the voyage out.

THE Silver City (Idaho) Avalanche, says: "The prospect for lively times the coming spring are decidedly brighter than ever before known in this camp. All the mines on War Eagle mountain were never in such good shape for yielding large quantities of good ore as they are at present, and preparations are being made for a vigorous mining campaign during the coming summer."

SOCIETY ISLANDS.—A correspondent asks us the rates of fare to the Society islands by steamer. No steamer runs there, but schooners leave here for the islands about once a month, the fare on which is \$75. The islands are about 30 days' sail from this port.

THE partnership heretofore existing between W. A. Go dyer and I. A. Blake, civil and mining engineers, has been dissolved. Mr. Goodyear is now to be found at room 76, No. 120 Sutter street, and Mr. Blake's office is at room 10, Mercantile Library building.

THE Central Pacific railroad company has declared its second dividend. This one is six per cent., aggregating \$3,256,530, or \$6 per share.

We have received from A. L. Bancroft & Co. "Brush's Determinative Mineralogy and Blow Pipe Analysis," a short review of which appeared in last week's issue.

Among the Foundries and Machine Shops.

Of the work accomplished at our machine shops since the last issue of the PRESS we notice the boiler for the steamboat *James M. Donahue*, made at the

San Francisco Boiler Works,

And placed in position on Saturday last.

This boiler is the largest ever constructed on the Pacific coast; the diameter of the shell is 11 feet, 6 inches; 14 feet across the front; length of boiler, 23 feet, 6 inches; height from bottom of boiler to top of chimney, 26 feet, 8 inches; height of smoke-stack, 40 feet, diameter, 52 inches; weight of boiler, 46 tons. The type is, a flue and return tubular. It is designed for either wood or coal.

In this connection we might speak somewhat particularly of the *Donahue*. She is built to the order of Mr. Peter Donahue, and designed to run from this city to Donahue in connection with the Northern Pacific railroads. She is a side-wheel steamboat of 750 ton burthen; 220 feet long; breadth of beam, 32 feet; depth of hold, 9½ feet. Being intended only for a day boat, she has but six staterooms, four of these being large and intended for family, or, in steamboat parlance, "bridal rooms," located in the forward part of the main saloon. The lower cabin is fitted for a dining saloon. The upper or promenade deck is covered, and extends forward and aft 180 feet, its interior furnished and ample light afforded by windows on the sides. The cabin front and dining saloon will be hard wood finish; the interior of the main and of the upper saloon is to be done in white and gilt. The engine is of the vertical beam pattern. Diameter of the cylinder, 48 inches by 11 feet stroke. The wheels, of the composite type, are 28 feet, 6 inches in diameter; width of buckets, 8 feet; depth of buckets, 24 inches. The *Donahue* is a finely modeled, roomy boat; will be fitted with all the appliances necessary for the comfort and safety of passengers, and will be a credit to our naval architecture. Her construction has been under the general supervision of Capt. W. W. Vanderbilt, for a quarter of a century in the employ of the P. M. S. S. Co., and for a good portion of the time their general superintendent. The hull was designed by Mr. Wm. A. Collier, Mr. Daniel Ross is executing the wood and carpenter work, and Capt. Wm. Gallaway acts as overseer. It is expected that the *Donahue* will be ready to take her place in the line about the middle of April.

The San Francisco works has also a large amount of miscellaneous work on hand, in different stages of completion, among which we notice the following: Two steel boilers for the Bay sugar refinery, two boilers for the Golden Gate mills; nine miles of 24-inch water pipe for the Contra Costa water company; two boilers for the Miners' foundry; 1100 feet of 48-inch pipe for the San Leandro tunnel, and the tanks for the Palace Hotel, nearly completed.

The Hope Iron Works.

Mr. W. W. Hanscom, late of the *Ætna* works, is engaged in erecting a foundry and machine shop on the corner of Minnesota and Santa Clara streets, (Portrero). The building when completed will be 260 feet long by 40 feet broad, to be divided as follows: Machine shop, 160 by 40; foundry, 100 by 40. It is to be known as the "Hope" iron works. A boiler is in course of construction for this establishment at the San Francisco boiler works. Mr. Hanscom's reputation as an engineer and practical founder ensures the excellence of any work he undertakes. He intends making a specialty of vertical stationary and propeller engines, for yachts and small steamers. Mr. Hanscom hopes to have his works in operation within thirty days.

Galice Creek.—Concerning mining matters in Southern Oregon, the *Times* of last Saturday says: The weather of the past week has been rainy and disagreeable, so as to render prospecting and other mining developments almost out of the question. Several citizens of Jacksonville have returned from Galice creek, but report no further developments. There are about 150 people there at present; but large numbers are constantly coming and going, as the accommodations are not ample enough as yet.

H. G. CAVIN and **James Leathen** arrived lately from Cornucopia. They report the weather as having been very stormy, with several inches of snow at that camp when they left there. They speak very highly of the prospects of the camp, and predict for it a brilliant future.

The total yield of the Consolidated Virginia mine for the month of February was \$1,205,390. This and the payment by the company of a dividend of \$10 per share speaks well for the bonanza mines.

The Virginia City *Enterprise* advises miners and laboring men not to come to the Comstock range seeking work, as there are twice as many men there now as can at present find employment.

Coal as a Raw Material.

Professor Wm. H. Brewer, who was formerly connected with the California State Geological Survey, and now Professor of Agriculture at Yale College, delivered a very interesting lecture at the State University on Friday, the 12th inst., on "Coal as a Raw Material." We regret that our space prevents our giving more than a brief synopsis of the lecture. Professor Brewer is well known on this coast from his connection with the Geological Survey, and scientific matters generally.

Eleven years ago, the lecturer stated, he had delivered a course of lectures to the old College of California. He had not finished the subject on that occasion, so he would now partly complete the course, and also give some of the discoveries that had been made since that time. As the title of the lecture indicated, coal was to be discussed, not with regard to its common use as a fuel, but as a raw material out of which other substances can be made.

The Sun the Fountain-Head of Force.

It is now a well recognized fact that coal is of vegetable origin, made perhaps of swampy material, or of vast forests. It occurs in extensive strata, sandwiched in as it were between other kinds of rock, and not in veins, as silver, copper, and many other metallic ores are found. Its use as a fuel, although comparatively recent, has become so general that it need only be referred to. But, besides its use for this purpose, an immense number of substances are made from coal, many of which are worth more than their weight in gold. It is interesting to follow out the theory of the conservation of force in coal. This theory is, as its name indicates, that force is never destroyed, being simply changed from one kind of force to another. According to this idea the sun is the fountain head of all force on this earth. So that when coal is burned we are merely receiving the heat and light shed by the sun on vegetation in bygone geological eras. All forces used on this earth are derived from the sun, directly or indirectly, except the force of the tides, which has been utilized to some extent. In this State there is another variety of force not dependent on the sun, which may at some future date be rendered available, but which as yet is rather unmanageable—earthquakes. The force derived from the sun, through the instrumentality of coal, may be better appreciated when it is stated that it has been estimated that steam, at the present day, does this work of a thousand million men.

Coal consists principally of carbon, with which is united hydrogen and oxygen, together with some earthy matter, and is divided according to the amount of volatile matter contained, into anthracite and bituminous or soft coal. The former is used for fuel only, and the differences between the two are similar to those between charcoal and wood—charnel, like anthracite, burning with little blaze but intense heat.

Substances Made from Coal.

But the lecture is not to deal so much with the uses of coal for heating purposes as its uses for the manufacture of other valuable substances. These substances, although made from the coal, are not necessarily in it, as soda, which is not found in appreciable amounts in sea-water, is nevertheless made from the salt contained. So grapes contain juice from which brandy can be made; from the brandy, vinegar; from the vinegar in connection with lead, sugar of lead, and so on.

It is impossible to go into much detail with regard to the innumerable products resulting from coal. So only a few can be considered. Leaving out the use of coal for ornamental purposes in the form of jet, the principal products are the results of the distillation of the coal.

This distillation occurs in the gas works where the coal is heated in large iron retorts, and is separated into three parts, a solid part remaining in the retort as coke; a gaseous part, purified by passing through water, and other chemical substances, and delivered to the consumer finally, as common illuminating gas; and lastly, a liquid part; condensed in the water. Coke is not the least important of the products. It has a much greater heating power than bituminous coal, and in some parts of Pennsylvania it is made for smelting iron. As coke is used for galvanic batteries, it assists in carrying news around this world on the telegraph. As for gas, its uses are too well known to need mentioning.

Profit on Gas.

The cheapness of gas, considering only the cost of the necessary coal, is rather astonishing to one who has never thought upon the subject. A few years ago the lecturer had occasion to make some inquiries regarding the cost of gas in the Eastern States, and he found that in one large city, deducting the value of the coke, coal-tar, etc., from the cost of the coal, the gas cost but five cents per thousand feet, and it was sold in the same town for three dollars per thousand, though of course this was not all profit.

Coal Tar.

This substance, black, dirty, with a disagreeable odor, would seem to be the last substance in the world from which anything of value could be obtained. But by the researches of the modern chemists this disagreeable substance has been used in the production of compounds of great value, and approaching the

rainbow in brilliancy. Coal tar is sometimes used as such, for painting fences, railroad ties, etc., on account of its preservative properties, but commonly one of its products, carbolic acid, is used for this purpose. Ammonium salts are also made from this same substance in many places, and used either as manures or for manufacturing ammonia. The results of the distillation of coal tar, left in the retort, is called asphaltum, differing considerably from what is known by the same name in California, but being used for similar purposes.

There are many oils resulting from the distillation of coal tar, some of the light ones being used to produce local insensibility to pain, such as the freezing of the gum to which the dentist resorts. One of these light oils, benzol, exhibits in a remarkable degree the number and values of the coal tar productions. Fifty years ago, in 1825, Faraday discovered, while experimenting on coal tar, the substance now known as benzol. Twenty years after a French chemist found that when benzol was treated with nitric acid, a substance called nitro-benzol resulted, having the odor of bitter almonds, and now used for giving almond soap its odor. About the same time, a Dutch chemist discovered a beautiful blue color, while experimenting on indigo, and shortly after a blue solution was obtained, in alcohol, from nitro-benzol. It was soon proved that the two blue colors were of exactly the same constitution, and they were called aniline. They were regarded as curiosities, but no practical use was made of them, as there were many kinds of blue dyes, and much cheaper than aniline. But an English chemist, Perkins, while searching for a cheap method of preparing quinine from nitro-benzol, obtained a beautiful alcoholic solution, of a mauve color. This was found to be such an effective dye that numerous experiments were made on this substance, and the result is the production of considerably over three hundred dyes of different colors. The intensity of these dyes is most astonishing. A piece of some of them, the size of a pea, imparts a very perceptible color to a hoghead of alcohol.

Many have thought that practical discoveries could only be made by practical men, but the discovery of the aniline dyes shows how far this is from being correct, as they were found by men working in the pure science.

Professor Brewer delivered another lecture yesterday on "Western Explorations."

Notices of Recent Patents.

Among the Pacific Coast patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

FLUX FOR TREATING ORES.—P. N. Meckay, San Francisco, Cal. This invention is an improvement in the flux for treating ores, patented in December, 1873, by the same person. The improvement consists in combining the mineral cryolite with the crude borax or any of the borates, silica and chloride of sodium, claimed in the former patent, in preparing the flux. For instance, in purifying iron or steel containing an excess of silicon, the inventor uses two per cent. of either of the borates, two per cent. of cryolite, and five per cent. of chloride of sodium, mixed intimately together as a dry powder and injected into the molten mass through the tuyeres. In fact, this invention consists in the addition of from one to five per cent. of cryolite to the fluxes described in the former patent.

SECURING PROPELLOR BLADES TO THE HUB.—Jas. H. Loftus, Oakland, Cal. This invention is an improvement on the construction of propeller blades, and in the method of securing the same to the hub, so that they will be greatly increased in strength and can be replaced when necessary. The usual manner of forming the propeller is to cast the hub and blades in one piece, but in this improvement the hub only is made and secured to the propeller shaft. In the face of this hub are formed wide slots, parallel with its axis, and of sufficient width and depth to admit of as great a thickness of metal as may be contained in the part of the blade which is fitted to the slots, and also the bracing plates to be used. As many slots will be made as there are blades to the propeller. The propeller blades are formed of sheets of metal of sufficient thickness to withstand the pressure.

LIQUID MANURE.—Chas. H. Hoffman, San Francisco. This is an improved compound for fertilizing the soil, and which is also useful for germinating seeds, and for protecting seeds and plants from the ravages of insects, moles, and such small animals as are destructive to vegetable life. The inventor claims that this manure will cause vines and trees prepared with it to mature two or three weeks sooner than usual and will bear fruit sooner, and of a better quality.

WAGON BRAKE.—John Grider, Milton, California. This is a device to be applied to the brake beams of wagons and consists in the use of a partial socket or cap of cast-iron which is bolted to the end of the brake bar and has formed with it a fixed jaw and a movable jaw which holds the brake shoe. A slot being made in the face of this cap, the movable jaw enters this slot and a screw from the outer end of the brake bar serves to operate the jaw and causes it to clamp the brake block firmly against the fixed yard.

Terraces in the Coast Range.

Related to the Delirius of Glaciers, and of the Ancient Rivers.

At the last meeting of the California Academy of Sciences, Mr. Amos Bowman (late of the late Geological Survey) read the following paper:

On the subject of the Pliocene sea—in other words the Pacific ocean—as it stood with reference to the continent of America, during the accumulation of the ancient river, or hydraulic mining gravels of California, a remark from me called for at this time, in order to prevent persons interested in this line of facts from falling into error. In my examination of this subject on behalf of the State Geological Survey, no fact was more clearly made out than that the ice period occurred ages later than the ancient river filling period. The most inexperienced observer, if honestly looking for the facts in the case, within the region of the Sierra Nevada covered by both the Pliocene river gravels and the glacial detritus would be obliged to stumble upon some fact or other in proof of this every day.

Yet Prof. Davidson, Dr. Willey and the late editor of the "Overland," have each promulgated as the causes of the ancient river gravel accumulations the ice phenomena of a period comparatively recent. Prof. Davidson pronounces the ancient river gravels at Smartsville glacial morain. There is no glacial detritus within thirty miles of Smartsville, nor within 1,000 feet of that altitude, which is but 750 feet above the sea.

Prof. Davidson, in his capacity of Assistant in charge of the Coast Survey on this coast, several years ago mentioned to me several localities additional to those enumerated by Blake and Newberg in the United States Pacific Rail Reports, where terraces existed at high altitudes along the coast. As I had just then revised the relation of the ancient rivers to the sea of the San Francisco peninsula pliocene, and was following the latter to its connection with certain ancient river deposits of the Coast Range, intermediate between the present sea and the Sierra Nevada, I urged Prof. Davidson very strongly to write out and present to the Academy a list of these terraces, in order that he might be aided by their additional testimony along with the anfrictuous deposits lying so high up on the flanks of the Sierra. He did so, I was much pleased to see, in a highly valuable paper; but not content with a straight and simple statement of the facts, he proceeded to build up an original theory. This theory was in broad terms that the ice made these terraces. He does not state that he visited any of the terraces in Oregon or California in search of strata and *roche moulées*. On the other hand he distinctly does not commit himself to anything of the sort.

The fact is that these strata do not exist anywhere near the coast terraces, south of the Columbia river. North of the Columbia, the great ice cap of the cold period reached down to the sea, and every hillock and mountain is rounded and polished, or striated. Prof. Davidson had both land glaciers and icebergs, that floated in the sea, to account for his terraces. If the one should be proven to be unreal or impossible, the other could be fallen back upon.

In order to make out the glacial or land ice (not iceberg) theory, however, he deemed it necessary to declare first that they were not sea terraces. I had at that time stated to the Academy the facts with regard to the position and altitude of the San Francisco and Coast Range pliocene terraces, so that he had to ignore, in order to make out his theory, all these, and other important facts accepted by the geological survey, as stated by me to the Academy.

Prof. Davidson in this article perpetrated the thoughtless inconsistency of denying that the sea level had anything to do with these ancient terraces, yet at the same time promulgating that they were formed by icebergs, that must have floated in the sea, or land glaciers that at these levels went into the sea.

Another error in this connection has gone on the records of the Academy. Dr. Cooper, at a recent meeting of the Academy, presented a resume of the geology of the pliocene period, which I am sorry I was not able to listen to. Every contribution of fact on this subject is of the greatest scientific value to all interested in the geology of California for many reasons. The Doctor's remarks, as published from his manuscript in the MINING AND SCIENTIFIC PRESS, are unfortunately very general, embracing little that had not already been published or made accessible in the library of the Academy. While the definite tangible line of facts in his address, on which, one might actually take hold, consisted in his delineation of the outlines of the pliocene sea on the State map. The map hangs there, on the wall, but the red paper strips and tacks that were pinned upon it are no more. How are we to profit by the Doctor's contribution if we would give it the closer attention and scrutiny that the subject deserves? I trust and hope that he will do the Academy the service of coloring the map, or

at least drawing faint red lines, which will improve and enhance the value of the map.

Dr. Cooper recognizes this pliocene sea which Prof. Davidson ignores, as having left its marks on the peninsula of San Francisco. But Dr. Cooper does me the honor to say that the terraces at altitudes of 700 and 1,000 feet, which were described by me in the proceedings of the Academy two years ago, as occurring at the same levels as the pliocene beds to which I referred, terraces so abundantly confirmed by Davidson's testimony a year later, were seen by me only in imagination.

According to Dr. Cooper, Prof. Davidson then saw his terraces only in his doubly-large imagination; for Prof. Davidson reported twice as many as I did, as he saw them from the sea, and some of his were twice as high as mine. To make it clear to the Academy that the facts heretofore reported by me on this subject of terraces were imaginary, the Doctor points out that I failed to observe that the strata of the San Francisco pliocene dip very considerably towards the sea, northwest; consequently, according to Dr. Cooper, it is a mistake to suppose that there could be any terrace on the surface. He admits the pliocene age of the rock, and also the fact that seen at a distance the formation would probably look, to eyes less

newer than the miocene is established by the fact that they lie and surface also the miocene hills high up in the Coast Ranges. Being thus limited between the miocene and post pliocene, they cannot have been anything else than pliocene.

The significance of the geology of the pliocene period on the Pacific coast is immense. The most wonderful system of extinct rivers delved into and laid bare for miles to the bed rock, and even to the deepest gutters and "pot holes, by the hand of man (on account of the fortuitous circumstance of their containing gold); rivers flowing in the middle tertiary from a mountain's side, into which they had eroded canyons over a thousand feet deep; which, then, in the period of which we are speaking, in a tropical climate, with heavy rainfall, became suddenly the agency for the deposition and storage, so to speak, of a continuous eurytherous, sedimentary formation, extending from the margin of a shallow sea, fifty to seventy-five miles inland, to points on the very shoulders of the Sierra Nevada, 6,000 feet above the sea.

They drained valleys inhabited at the time by the human race—as is made out with a fair showing—at a time when none of the present species of mammals beside man were yet created. To admit, as Dr. Cooper did, that the

vegetation, washed by the waves of many great fresh water lakes, like those of Camasa; and that the mighty proportions of the stuken continent of the Pacific ocean, outlined by Dana in the "Wilkes' Exploring Expedition Reports," was then, under the eyes of the ancient Californian, a reality, not yet quite given over to the coral insect and the geologist to be rescued from oblivion, but visibly in process of undergoing a downward movement, corresponding to, and probably coterminous with, the upward movement of the great Cordilleran plateau, the date of which we are thus enabled to fix.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last. Henry R. Taylor and J. W. Anderson were elected resident members. The donations to the museum were unusually light, and were embraced in a few botanical specimens presented by John Muir, and a section from the branch of the *sequoia gigantea*, presented by Mr. Turrill. A few Government scientific works were added to the library—and also a rare volume entitled "The Universal Geography," printed in London, in 1711, and abounding in quaint illustrations, maps, etc. The book was recently presented to Commander J. S. Skerrett, of the United States Navy, by His Excellency John O. Dominis, Governor of Oahu, Hawaiian Islands. The book is printed in Latin. Also a copy of Commander Belknap's "Deep Sea Soundings in the North Pacific Ocean."

It was announced to the Academy that the completed work of the State Geological Survey, as far as regards the botany of California, would shortly be published, through the exertions of certain gentlemen of this city.

Charles Wolcott Brookes, Japanese Consul, read an extended and interesting paper on the Commerce of the Ancients. This is an introductory paper, as the author intends following it up by giving an account of the commerce of Japan and China, while investigating the origin of the Japanese.

Amos Bowman read a paper which is given in another column of this issue.

Dr. C. B. Brigham read a communication describing the arrangements adopted for the "International Congress of Americans," first session to be held at Nancy, France, from the 19th to the 22d of July next.

Judge Hastings called the attention of the Academy to the fact that some persons at the East had published a book giving the same explanation of the so-called spiritualistic phenomena as presented by himself to the Academy months ago, ascribing it to the action and influence of the imponderable ether. He believed that larceny had been perpetrated in some form, as no other person could possibly have reached the discovery originally promulgated by himself. The Secretary of the Academy, in answer, said that the Publication Committee had refused in every case to publish the papers submitted by Judge Hastings, and that his effusions had been carefully locked up in the Secretary's desk, so that they should be prevented from reaching publicity through the proceedings of the Academy. This rather spoiled the Judge's theory that his ideas had been stolen.

A Rustic Shelter.

The accompanying sketch is of a rustic shelter erected in 1872, by Mr. Anton Gerster, on the shore of the large lake in Prospect Park, Brooklyn, N. Y. Its dimensions are 28x16 ft. Posts, railing and plates are of sassafras timbers, twelve inches in diameter.

The octagon portion is enclosed with slips of red cedar, with ceiling boards between, making a perfect tight roof. The inside is a high ceiling as shown in the plan.

The ridge is of rustic ornaments. In short, the plan is a working one, showing on the left, the inside with seats and ceiling finish, on the right, showing the outside finish. The seats are in the octagon portion, which gives seclusion to those wishing to rest there, and to others an opportunity to look from the back and front without interrupting those who are seated. It is also used as a station for the boats plying on the lake; hence it is useful as well as ornamental. It was erected at a cost of about \$1,500 by day's work. There are many places in and around San Francisco and Oakland where such a work would be very becoming. There is also very suitable timber for rustic purposes not far from here which would enable the artist in rustic to build at most reasonable rates. A structure of this style would add greatly to the attractions of Woodward's Gardens.

The average daily ore product during the past week from the Consolidated Virginia mine was 350 tons; from the Belcher, 450 tons; Crown Point, 400 tons; Ophir, 150 tons; making a total daily yield of 1,450 tons of first-class ore from four mines on the Comstock.

THE Act passed by the Legislature of the State of Nevada at their last session, concerning the taxing of the mines on the same basis as other property, will have the effect of increasing the valuation of taxable property in Storey county from \$5,000,000 to \$18,000,000.

A RUSTIC SHELTER.

geologically level than his own, like a terrace. His idea of the "true pliocene terraces" is that they are to be found only low down, near the levels of the present bay or ocean.

Dr. Cooper simply errs in accepting the word "terrace" as signifying the same thing as a bed or stratum. Instead of making out a

Table mountain skulls and stone implements were found under a lava flow, but to ascribe to them a later than a pliocene date, would be to assume that the lava flows continued in places throughout the glacial epoch; and accompanied by washed gravel and water, sought and followed down what are now ridges of the

GROUND PLAN.

case of superficial observation of fact on my part, in the present case, he has made out a case of superficial interpretation, and misuse of geological terms, by himself.

My whole line of facts related to terraces, not to strata; to surface lines and surface deposits, as determined in age by the underlying beds, or strata containing fossils. The terraces followed these beds in order of time. They were formed by a receding sea. That these terraces were not older than the pliocene is evident from the fact that they form the tops and sides of the pliocene hills, and that they are as old as the pliocene is very fairly inferred from the fact that the sea had not receded to any "low levels around the bay" at all, until ages later; when the ancient rivers had become extinct and the volcanic outflows had marked another intervening period, and the glacial phenomena still another long lapse of time preceding the recent, in which we live.

Such being the case, no "true pliocene terraces" can have existed at low levels around the bay. The Doctor meant pliocene beds when he talked about terraces. The terraces that exist at low levels around the bay and along the coast, are post pliocene and recent. That the high terraces, described by me and by Professor Davidson, are older than the post pliocene, is further demonstrated by the fact that no post pliocene sea ever left any shells at such altitudes. The pliocene sea did, as I showed. That those terraces are generally

Sierra, precisely like those of the ante-glacial rivers. The evidence in general of the succession and newer date of the cold period however, is, as remarked, so clear, that Cooper's hypothesis is worthless unless it can be supported by some fact demonstrating that these lava blocks, accompanied by washed boulders, overlay in some places, the moraines and striated rocks; which would be something new, to me at least, and I think, to all other students of these phenomena. He would have to claim that the river of Table mountain left its old bed at a later period than the other rivers of the Sierra; that the canyons of the Stanislaus and the Mokelumne were begun upon by these rivers, at a later period and under different conditions with regard to erosion and filling, than the other canyons of the Sierra.

The testimony of these pliocene sea terraces is, that the whole Pacific coast range, and probably also the great basin or plateau of the interior, for a thousand miles at least, has risen since the advent of man (if the doctor's admission concerning the Calaveras skull be accepted) to an average in places of fully a thousand feet; that the States of California, Oregon, Washington and Arizona were more than half engulfed under brackish or salt water seas at the same time—such as are still in existence on the shores of British Columbia and Mexico; that the mountain water lines of Salt Lake and the great basin of the interior were, during this same period, of tropical precipitation and

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they
 have no equal. No effort has been, or will be spared
 to have them constructed in the most perfect manner
 and of the great number now in operation, not one has
 ever required repairs. The constant and increasing de-
 mand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly
 into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces
 the pulp to the center, where it is drawn down through
 the aperture and between the grinding surfaces.

Thence it is thrown to the periphery into the quicksilver.

The curved plates again draw it to the center, where it
 passes down, and to the circumference as before. Thus
 it is constantly passing a regular flow between the grind-
 ing surfaces and into the quicksilver, until the ore is
 reduced to an impalpable powder, and the metal amal-
 gamated.

Settlers made on the same principle excel all others.

They bring the pulp so constantly and perfectly in
 contact with quicksilver, that the particles are rapidly and
 completely absorbed.

TABLES OF MINERALS.

Tables for the Determination of Minerals by their
 Physical Properties. Translated from the German of
 Welsbach. Enlarged and furnished with a Set of
 Mineral Formulas, a Column of Specific Gravities,
 and one of the Characteristic Blowpipe Reactions.
 By PENSIOF FRAZER, JR., A. M., Member of the
 American Philosophical Society, etc. 12mo. Roan
 limp \$2.00.

"We have here an exceedingly useful and compendi-
 ous guide for explorers, who frequently have to pro-
 nounce on substances in situ, where no laboratory is at
 hand. The eminent author gives many new lights on
 classification, and his aim has been throughout to
 render the science of mineralogy as clear and accessi-
 ble as its complicated nature will permit. The trans-
 lator's work has been done faithfully and intelligently."

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR
 APPLICATION—requiring no thinner or dryer, and will
 not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and pro-
 duces a more Beautiful Finish than the best of any
 other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will
 last twice as long as any other Paint.

In ordering White, state whether for Outdoors or In-
 side use, as we manufacture an Inside White (either
 Flat or Gloss) for inside use, which will not turn yel-
 low, and produces a finish equal to the finest China
 Gloss.

Put up in 1/2, 1, 2 and 5 gallon packages, and in
 Barrels. Sold by the Gallon.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
 Price Reduced to 16 Cents Per Pound.
 SAN FRANCISCO, November 10th, 1874.
 To Super. of Quartz Mills and Mining Men generally:
 We take pleasure in stating that owing to the rapid
 increase in our orders, our Pittsburg Manufacturers
 have been compelled to add largely to their works—
 a new gas furnace and heavier trip hammer—and are
 thus enabled to reduce the cost of steel and at the
 same time produce SHOES AND DIES superior to any yet
 manufactured. We have consequently reduced the
 price to 16 cents per pound and solicit a trial order,
 guaranteeing that you will find them at least 10 per
 cent cheaper than the best iron. There are no STEEL
 SHOES AND DIES made excepting under our patent and
 sold at this office, or by our authorized agents, though
 certain Eastern manufacturers advertise STEEL SHOES
 AND DIES which are only cast iron hardened by the
 addition of a composition. They will not out-wear two
 sets of common iron, though called steel. They are
 very brittle and are not capable of being tempered,
 flying from under the hammer like cast iron. Our
 STEEL SHOES AND DIES are in use in many of the largest
 mills on the Pacific Coast, and all who have tried them
 pronounce them cheaper and far superior to iron in
 every respect, even at the old price of 20 cents per
 pound. Their advantages over iron are cheapness on first
 cost, increased crushing capacity, time saved in chang-
 ing and in setting tappets, increased value of amalga-
 mation, absence of iron dust and chippings, and a saving of
 75 per cent. in freight. It takes 50 days to fill orders
 from the manufacturing East. Price 16 cents per
 pound shipped at San Francisco. Terms liberal.
 Address all orders, with dimensions, to

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE
 For Roasting, Desulphurizing, Chloridizing
 and Oxidizing Ores, etc. For the reduction of
 Gold, Silver, Lead and other ores, saving a larger per-
 centage, at less cost, than any other invention now in
 use. Chloridizing Silver ore more thoroughly, in less
 time, with less fuel, salt and labor; also roasting Lead
 ore preparatory to smelting, better and cheaper than
 any other invention. The Furnace is so constructed
 that one man, of ordinary ability, tends five or more
 furnaces; controls them with ease; adding heat or air;
 stopping or starting at will; charging and discharging
 with ease. Also, Patent "Conveying Cooler," for con-
 veying and cooling roasted ores, heating the water for
 amalgamation and the boilers at the same time. Saving
 the large space in mill (covered with brick or iron),
 and the labor of two men per day, exposed to the poi-
 sonous chlorine gases. Also, Patent, Air Blast "Dry
 Kiln," for drying ores direct from the mine or breaker,
 saving fuel and labor heretofore necessary in drying
 ores for dry pulverizing. For description refer to
 MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874.
 For particulars address
D. B. MILLER & CO.,
 No. 12 West Eighth Street, Cincinnati, Ohio
 Circulars, &c., will be furnished, if required.
 18v29-3m

CROCKER'S PATENT
TRIP HAMMER QUARTZ BATTERY.

 This machine, complete, weighs 1,500 lbs. Has an iron
 frame, five steel arms with stamps weighing 17 lbs. each,
 which strike 2,000 blows per minute, in a mortar provided
 with screens on both sides, and crushes FINE 600 lbs. per
 hour, requiring one-horse power to drive it. Has been
 thoroughly tested, and is guaranteed to give good satis-
 faction. PRICE, \$600.
G. D. CROCKER.

Abandonment of Claims.

The mining suit referred to in our last week's issue is one of general interest to the mining community, as it proves that people cannot abandon their claims, and then, when other parties prove their value, come in and reap the reward. This has very frequently been done before this, and has tended in a great degree to prevent the sales of mining property. People who buy claims want them clear of all incumbrances or clouds to title; and it has been unfortunately the case that in many instances former owners have asserted that they had never abandoned the claims and sued for possession.

Judge Wallace in his instructions to the jury in the Geyser quicksilver mine case said: "If the jury believe from the evidence that the plaintiff or his grantors left the premises in controversy vacant and unoccupied for a series of years, and during that time exercised only casual acts of ownership upon the claims at long intervals, and that during that time no actual work was done toward working or developing the mine, either upon or in proximity to the claims, and that the defendants finding the ground apparently abandoned, entered upon and located the same in pursuance of the mining laws of the district and the laws of Congress, and have continued to comply with said laws, and have in good faith, reasonably believing said ground had been abandoned, expended large sums of money in developing said mines, then you are authorized to find the fact of abandonment."

This is perfectly just and should be remembered by all miners.

The Judge also said: The failure of a miner, upon the public land of the United States, to do the amount of work or spend the amount of money upon his claim, required by the local rules within a time appointed on pain of forfeiture will not of itself take away his mining right, but the ground must be duly relocated in a lawful mining district and with the proper recorder thereof (when record is required by its law) before his right can be taken away for such failure; and if he begins to do the work or expend the money required before his ground is so relocated his preceding failure in either respect is cured. The jury are instructed, that where a party relies upon mining rights acquired by mere occupancy, possession, appropriation and work, such rights continue so long only as the claimant continues the enjoyment or shows an intention to continue it. Such parties may lose their rights by abandonment of them if he indicates an intention when he relinquishes the enjoyment of them never to resume it.

The ceasing to enjoy mining rights acquired by mere occupancy and appropriation, whether depending upon prior actual possession or compliance with mining customs, will destroy the rights, provided the discontinuance be absolute and decisive and unaccompanied with any intention to resume them within a reasonable time.

Where a party relinquishes his possession of mining claim with no intention to resume the possession or to work the mine in good faith, or to subject the same to appropriate uses, but lies by and suffers the premises to become apparently vacant, disused and abandoned, and thereby induces others to appropriate the same in the reasonable belief that the same are unclaimed and subject to appropriation, and then intending only in the event that such mine is shown to be valuable by the labor and expenditure of such subsequent appropriation, to assert a claim thereto and endeavor to obtain the possession thereof, and others to appropriate and develop such mine in the reasonable belief it is vacant and unclaimed, induced thereto by the acts of prior claimants, such prior claimants will be held to have abandoned the same. If the jury find from the evidence that the plaintiff or his predecessors had forfeited their rights to the mining ground sued for, and that after such forfeiture and while said ground was unoccupied the defendants or their grantors, entered under the rules of the district and located said ground and have since continued to occupy the same and have complied with the rules and regulations of the district, then you will find for defendants. In considering the question of forfeiture, the intention of the person claiming the ground is entirely immaterial. As the suit was decided in favor of the defendants, it is probable that the jury considered that the ground was abandoned, and that the other locators were entitled to possession.

LARGE MAGNETS.—The Sheffield Scientific school, New Haven, has received an important addition to its philosophical apparatus in the form of an immense electro magnet, together with all its appropriate accessories. This splendid instrument was a present from William Wallace of Ansonia, by whom it was constructed. There is only one larger instrument of the kind in the country, perhaps in the world. This was also made by Mr. Wallace, and was purchased by the Stevens Institute of Technology, at Hoboken. It weighs altogether nearly half a ton, and is capable of lifting, it is said, twenty times that weight, or over ten tons, when in full action. The public, it is presumed, will have an opportunity of seeing it in operation before long, as one of the lectures in the mechanics' course, now going on at the school, is on the subject of magnetism.

Agricultural Items.

THE Sherman Island overflow occasioned the destruction of a large area of grain, but as the water is receding the farmers are hopeful that they may yet grow a crop of potatoes the present season. A portion of the land will doubtless be drained in season to make a crop of hay. Above Mayberry slough the wheat crop never looked more promising. The grain is tall and thick and will be considerably earlier than usual.

THE Petaluma *Argus*, of the 12th inst., says: Between five and seven thousand sacks of potatoes are now stored in the different warehouses in town. Last week over seven thousand sacks were shipped to San Francisco, an unusually large quantity for this time of the year. Farmers are at present hauling potatoes to town in moderate quantities. The price paid by dealers is \$1.50 per one hundred pounds.

EXPENSIVE LEASE.—Farm leasing in the Eastern States is generally resorted to by those who lack means to buy even the cheapest farms. Here it is otherwise. A farm in this State consisting of 20,000 acres has just been let for five years at an annual rental of \$40,000. The farm is stocked with 1,900 head of cattle, 100 horses, 50 mules and 1,500 hogs, costing the lessee, with crops, \$74,250.

The contributions of wheat from the United States to the bread supply of Great Britain in 1874 constituted 55 per cent. of the whole imports, and those of Russia 13 per cent. The aggregate export of wheat and flour from the United States to Great Britain during the year exceeds an equivalent of 52,000,000 bushels.

REFERRING to the Stockton wheat market, the *Independent* says: It is estimated there are at least eight thousand tons of wheat still remaining in the warehouses of Stockton, two thousand tons of which have been sold for shipment. The market is dull at present, particularly so for wheat of an inferior quality.

A New irrigating district is soon to be formed in Los Angeles under the Bush irrigation law, which will include Anaheim and the surrounding country to the extent of 12,000 acres. The water will be brought from Santa Ana river. This will be the second district formed under the new law, and will bring in all about 26,000 acres under irrigation.

This is the way that trees grow in Los Angeles county, according to the *Los Angeles Express*, which says: "The eucalyptus trees at B. D. Wilson's park, Wilmington, are only one year old from the seed, and have attained a height ranging from eight to fifteen feet, and a very luxuriant growth of branches and foliage."

A REPORT from Sierra valley says the soil is in excellent condition for plowing, and farmers all over the valley are getting in their grain. Crops will depend entirely upon the spring rains. Unless there is a good supply of rain the hay and grain crops will be complete failures.

A GENTLEMAN who has an eye to the abundance of the earth, and who had his weather eye open while passing through green fields, says that more promising grain than is now growing on the Denniston Rancho was never seen in that locality.

ABOUT 15,000 acres of grain have been planted this season in the Borden settlement, Fresno county. Of this amount, Major Reading, Friedlander, Major Holmes and Mr. Hall have about 6,000 acres. Grain is looking as well as could be desired.

THE Sacramento Sugarie has all its beets sowed, and most of them are above ground. The area laid down this year to sugar beets, by this company, is larger than ever before; and they look for a better yield than usual.

THE Bluzome ranch was sold yesterday at Santa Rosa, by Sheriff Latapie, at auction, for \$20,000, the Bank of California being the purchaser. The ranch is a portion of the Casalamuyomi grant, recently patented.

SANTA ANITA RANCHO, one of the finest ranches in Los Angeles county, comprising an area of 8,500 acres, has been sold to E. J. Baldwin, of San Francisco, for \$200,000, cash.

THE grain-field on all kinds of land in the vicinity of Marysville, Yuba county never looked more promising. Some of it is so stout that it will lodge before cutting time.

THE San Mateo *Gazette* is authority for the statement that in the San Pedro valley, near School House station, the potato blight is showing itself.

FARMERS in Borden settlement, Fresno county, have begun to irrigate their fields. They have planted this season about 15,000 acres of grain, and it is looking finely.

A BIG canal to drain the tule land in Big Meadows is talked of by the owners of swamp and overflowed land in that section.

BETWEEN five and seven thousand sacks of potatoes are now stored in the different warehouses in Petaluma.

TULE fire are now in order, the tules now being in the best condition for burning preparatory to cultivation.

THE crops at Half-moon bay are most encouraging.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

SUBSCRIBERS who by mistake get two copies of this paper, should notify us without delay.

Industrial Items.

ARTICLES of incorporation were filed in the San Joaquin County Clerk's Office last week by the San Joaquin and Fresno water company. The purposes of the company are the construction and maintenance of a canal and other works to divert the water of the San Joaquin river, and convey it through the counties of Fresno, Merced, Stanislaus, San Joaquin and Contra Costa, for the purposes of agricultural transportation and mining.

WE LEARN from the *Visalia Delta* of the 11th inst., that artesian water has been struck in the Mussel Slough country, the water rising two feet above the surrounding country. The pipe is in tough clay, and when this is penetrated it is believed a strong flow of water will be the result.

CASINOS for fifty box cars for the Northern Pacific narrow gauge railroad are being made at the Vallejo foundry. They include all the iron work except the wheels, which are obtained from the East.

MR. W. H. MARTIN, of this city, has gone to Kansas to escort a colony of about fifty families to this State. They have had an agent in the State for weeks hunting up a location, but it will not be fixed until the arrival of the colonists.

THE Santa Cruz *Sentinel* of the 13th says: The two foundries and two planing mills in Santa Cruz are busy turning out machinery and doing work for the two railroads now being constructed into town.

It is reported probable that a starch factory will be put up near Loma by another season, for which the enormous potato crop of that section will furnish staple.

It is predicted that the number of elegant residences erected in San Francisco during the year 1875 will exceed that of any previous year.

A COMPANY has been organized and a woolen mill is to be erected at Petaluma, and in running order by May.

THERE are very strong probabilities of Santa Cruz having an outlet by rail via San Mateo.

General News Items.

LETTERS from the Isthmus say that Commander Lull's survey for a canal route is proving very satisfactory, but reaching results both promising and unexpected. The Chagres river cannot be made available except as a valuable feeder, nor is a tidal canal feasible. The summit cut needs to be only five and a half miles long, with a mean depth of cutting of only fifty feet. The water supply is found to be bountiful.

THE Virginia and Gold Hill papers report that large numbers of immigrants from the East are flocking to those places. Drawn thither by stories of the "bonanzas." They are mostly destitute, and as there is no work for them, they would have done much better to have remained at home.

A MAN fell into a vat at the San Francisco Sugar Refinery a few days since. Luckily he caught by his hands, and only his lower limbs were badly scalded. Had his injuries proved fatal his body would have proved a sweet morsel for the coroner.

Two Yuba blacksmiths got into a quarrel in Marysville Saturday night, and one named Stoddard shot his companion, Glenn. The wound is a serious one. Rum the inspiring cause.

Most glowing accounts of the gold prospects continue to arrive from the Black Hills. Government still adhere to its purpose to keep miners out of the district, however.

POSTOFFICE circular instructions show that the recent legislation has fixed postage on transient newspapers at one cent per ounce.

JOHN MITCHELL has been returned a second time to Parliament from Tipperary.

WHALING operations along the lower coast have proved very successful this season.

E. P. WELCH, a condemned murderer, escaped from the Inyo county jail the 5th inst.

ARCHBISHOP McCloskey, of New York, is to be made a cardinal.

DUCK shooting since the 15th is unlawful.

A LARGE PROPORTION of United States and Foreign Patents granted to inventors on the Pacific coast during the past ten years, have been obtained through the agency of DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS. Our business was established in the year 1860. We have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington D. C., March 18, 1875.

FOR WEEK ENDING MARCH 2, 1875.*

TICKET CLASP.—M. Disney, Oakland, Cal.
TELEGRAPH SOUNNER AND RECORDER.—Daniel F. Leahy, Portland, Oregon.
CONNECTION FOR BEN BOTTOM SPRINGS.—Alex. C. McMains, S. F., Cal.
CANNLSTICK.—Wells Kilburn, Napa City.
FRUIT DAIRER.—Thomas C. Waters, S. F., Cal.
MUSIC LEAF-TURNER.—George L. Dimpfel, Benicia, Cal.
DOUBLE REVERSIBLE HINCE.—Edward Halsey, San Jose, Cal.
PRESERVING APPARATUS.—John P. Schmitz, S. F., Cal.

TRADE MARK.

For Watches.—J. W. Tucker, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph) in a paper, at the lowest rates. All patent business for Pacific coast inventors transacted with effect security and in the shortest time possible.

Hints about Advertising.

If you have goods to sell farmers, how much better will it pay you to advertise in a farming paper, closely read by 15,000 intelligent farmers, than in miscellaneous daily or weekly journals with 30,000 readers, comprising only 2,000 farmers. A mining journal in California with 15,000 readers reaches more intelligent miners than any other 10 papers in the Union.

Purchasers are more likely to look for information in the advertising columns of a paper devoted to their special interests, than elsewhere, when ready to buy. Some will not read advertisements upon any other occasion, but seek the best paper when wanted.

If you happen to be the only advertiser in your line of business in a paper, all the better. But if several firms advertise the same, your own judgment will question whether you can best afford to go unrepresented.

Weekly journals are read most leisurely and carefully, and at a time when the subscriber is most favorably inclined to examine advertisements. The newspaper most specially representing your particular branch of industry is usually best suited to your patronage, and the most profitable medium you can employ.

An advertisement in an honest and handsome sheet is favorable to the reputation of the advertiser. The readers of the Press are a superior and industrious class, who are able to purchase and who seek to patronize the best and fairest dealing tradesmen. Advertising in cheap priced mediums (of limited circulation) is like buying goods at retail when you could as well take them at wholesale.

Information imparted to a list of superior and intelligent, and active, and industrious readers (naturally looked up to by others for information), is seed sown in good soil for the advertiser.

Fame and fortune are gained, nine times in ten, by liberal and judicious advertising.

Hints to be Remembered.

A note dated on Sunday is void.

A note obtained by fraud, or even from one intoxicated, cannot be collected.

If a note be stolen it does not release the maker—he must pay it.

An indorser of a note is exempt from liability, if not served with notice of its dishonor within twenty-four hours of its non-payment.

A note by a minor is void.

Notes bear interest only when so stated.

Principals are responsible for their agents.

Each individual in partnership is responsible for the whole amount of the debts of the firm.

Ignorance of the law excuses no one.

It is a fraud to conceal a fraud.

The law compels no one to do impossibilities.

An agreement without consideration is void.

Signatures in lead pencil are good in law.

A receipt for money is not legally conclusive.

The acts of one partner bind all the others.

Contracts made on Sunday can not be enforced.

A contract made with a minor is void.

RATES OF POSTAGE—Domestic Postage.

ON ALL LETTERS throughout the United States, 3 cts. for each half ounce or fraction thereof.

ON LOCAL LETTERS, 2 cts. per half ounce where there is a free carrier's delivery; other offices, 1 cent.

POSTAL CARDS, 1 cent., in the United States.

VALUABLE LETTERS may be registered by payment of a registration fee of 8 cts. in addition to Postage. Money can be sent with absolute safety by mail, by procuring a Money Order. The fees are: On orders not exceeding \$10, 5 cts.; \$10 to \$20, 10 cts.; \$20 to \$30, 15 cts.; \$30 to \$40, 20 cts.; \$40 to \$50, 25 cts.

PRINTED BOOKS, in one package, to one address, 1 ct. for each 2 ounces or fraction thereof, not over 4 lbs.

ON TRANSIENT NEWSPAPERS, or other Printed Matter (Books excepted), and on Circulars, Pamphlets, Book Manuscripts and Proof Sheets, Maps, Sheet Music, Chromos, Engravings and Photographs, 1 cent for each 2 ounces or fraction thereof, not over 4 lbs.

SEEDS, Cuttings, Bulbs, Etc., 1 cent for 2 ounces and fraction of 1 ounce, not over 4 lbs.

SAMPLES OF MERCHANDISE (Liquids excepted), Ores, Etc., Flexible Patterns, Paper, Envelopes and Blanks, 1 ct. for each 2 ounces, not over 4 pounds.

ALL TRANSIENT MATTER, except duly certified letters of Soldiers and Sailors, must be prepaid by stamps.

ON matter not above specified, same rate as Letters.

THE SCIENTIFIC PRESS.—This valuable journal entered upon the seventeenth year of its publication on the 4th of July. The steady advance in character, that every reader has noticed in the paper, renders it unnecessary to make any platitude of improvement, and the publishers simply content themselves with the announcement that they will continue to make their paper as interesting as possible. That it is interesting to a large class of readers, the wide circulation and extensive influence of the Press, is sufficient evidence.—*Pacer Argus*.

April, 1875, to pay the delinquent assessment, together

Office—Room 13, No. 319 California street, San Francisco

Geneva Consolidated Silver Mining Com-
pany—Location of principal place of business, City
 and County of San Francisco, State of California.
 Location of Works, Chino Mining District,

And in accordance with law, and an order of the Board of Directors, made on the second day of February, 1876, so many shares of each parcel of such stock as are owned by the above named parties at public auction at the office of the company, room 14, 302 Montgomery street, San Francisco, on Wednesday, the thirty-first day of March, 1876, at the hour of 12 o'clock, m., together with the interest thereon, to be paid by the said parties, day, to pay delinquent assessments thereon, together with costs of advertising, to the said parties.

I, T. MILLIKEN, Secretary.

Office, 302 Montgomery street, room 14, San Francisco, Cal.

Keystone Quartz Mining Company—Principal place of business, San Francisco, California. Location of works, Butte Township, Sierra county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors held on the 8th day of March, 1875, an assessment (\$2.00) on each share of the capital stock of the company, was levied on the capital stock of the corporation, payable immediately. In United States gold coin, to the Secretary, at the office of the company, on or before the 15th day of April, 1875, at San Francisco, California.

Any stock upon which this assessment shall remain unpaid on or before the 15th day of April, 1875, will be delinquent and the same will be sold at public auction, and unless payment is made before, will be sold on Monday, the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

LOUIS VESARIA, Secretary.

Office, Northwest corner Pine and Sansome streets, San Francisco, California.

Greens Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Grass Valley Township, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th day of March, 1875, an assessment (No. 2) of one dollar per share was levied upon the capital stock of said company, payable on or before the 15th day of April, 1875, to the Secretary, at the office of the company, Room 8, No. 315 California street, San Francisco, California.

It is further ordered, that any shareholder who has not paid on Wednesday, the 21st day of April, 1875, will be advertised on that day as delinquent, and unless payment shall be made before, with the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. NESMITH, Secretary.

Office—Room 8, No. 315 California street, San Francisco, Cal.

Silver Sprout Mining Company.—Principal place of business, San Francisco, State of California. Location of works, Knerange Mining District, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 7th day of March, 1875, an assessment of five cents per share was levied upon the

capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of said corporation in San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 16th day of April, 1875, will be delinquent, and the same, if not paid on or before the 16th day of May, 1875, is made herefore, will be sold on Thursday, the 16th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and sale.

T. B. WINGARD, Secretary.

Office—Room 13, No. 318 California street, San Francisco.

Theresa Mill and Mining Company.

Principal place of business, San Francisco, State of California. Office of the Company, Connelville, Allegheny County, California.

Notice is hereby given that at a meeting of the Board of Directors of the Theresa Mill and Mining Company, at its assessment of twenty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the Company, Room 13, 408 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 16th day of April, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made herefore, for sale at public auction, and unless payment is made herefore, will be sold on Thursday, the 16th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and sale.

T. B. WINGARD, Secretary.

Office—Room 13, No. 318 California street, San Francisco.

Office—Room 15, 408 California street, San Francisco.

Tuolumne Hydraulic Mining Company.

Principal place of business, city and county of San Francisco, State of California. Location of works, Tuolumne county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 21d day of February, 1895, an assessment of twenty (20) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 14, 302 Montgomery street, San Francisco.

Any stock upon which this assessment shall remain unpaid on the 25th day of March, 1895, will be delinquent, and liable for sale under the provisions of the laws of this State in that behalf made, and will be sold on Saturday, the seventeenth (17th) day of April, 1895, to pay the delinquent assessment together with costs of advertising and expense of sale.

Office, Room 14, 302 Montgomery street, San Francisco.

SEND FOR
Descriptive Circular
and Prices.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. For sale only at

PLANING MACHINES.

FOR REFERENCE.—BLETHEN & TERREY, Oakland; D. A. McDONALD & CO., S. F.; PACIFIC SAW CO., S. F.; BAKER & HAMILTON, S. F.; W. T. GARRETT, S. F.; BURNHAM, STANFORD & CO., Oakland; A. M. JEWELL & CO., South Point Mill; RICHARDSON & HOLLAND, S. F.

The advantages of this machine over all others are:

1. The wrought iron slotted head (with steel journals) which is slotted on four sides, admitting of rustic mortising and heading knives with planer knives.
2. The improved links and extra heavy gearing which allows the expansion of the rolls to double the extent of any other machine.
3. The manner in which we drop the matcher heads, unscrewing the brass matcher heads and raising the pall and lever, allowing the shafts to drop entirely out of way, converting it to a 24-inch surfacer, which is done in a moment, while with the old style it takes an hour's time.
4. The extreme simplicity of the machine, and the manner in which the pins are set in the grating, holding the board against the guide, and the shipping lever for feed and extreme length of the boxes which keeps the journals perfectly cool, and oil boxes in all the journals.
5. Ten years' experience in improving and perfecting this machine, having been in constant communication with leading mill men, and the ablest mechanics on the Pacific Coast, together with an experience of twenty-eight years in building wood-cutting machinery, I confidently assert that this machine possesses every requisite for a planing machine, and all that science and skill can accomplish has been bestowed on this machine to bring it to a degree of perfection hitherto unobtainable in any other machine manufactured; and I confidently challenge the world to produce its equal.
6. The above cut represents one of my smallest machines. I also build a two-roll machine, which is four-sided, adapted to planing mill use. Others with four rolls with or without underhead. Also a six-roll machine with or without underhead; and with or without a third matcher head for sizing the lumber, and many other machines as required.
7. My machine is the most simple, most durable, and less liable to get out of order; and are sold twenty per cent. less than any other machines ever sold on this Coast.

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.
(Covered by Letters Patent of July 2d, 1872, and recent applications.)

Containing a sizing apparatus, (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having five sieves, each row concentrating according to specific gravity the special size automatically fed out it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d class ores into 1st class ores of perfect cleanliness. It thoroughly separates native gold or copper from quartz or any other lode matter; galena and silver sulphate from pyrites, barite and quartz, and pyrites from quartz. Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

VOLUME XXX
Number 13

The District Telegraph.

In most of the large cities in the East, the district telegraph is an "institution" which can no longer be considered as an experiment, and its convenience to the public is such that it would be difficult to do without it. Until recently, no attempts have been made to inaugurate this system on this coast, but recently a company has been organized, the boxes are being made, and shortly San Francisco can boast of its equality with other great cities, in having its district telegraph. As this is an enterprise with which the public is likely to have intimate relations in the future, a sketch of its character and purposes will be interesting:

The object of the district telegraph is to place at the immediate service of each of its subscribers a specially trained force of messengers, watchmen and policemen, and to do all this at so low a price as to enable any one in moderate circumstances to avail himself of the company's services. The city is divided into districts of such size that the extreme points in the district can be reached in three minutes from an office situated in the center of the district, where there is a force of operators, clerks, messengers, firemen and policemen. A signal box, such as is shown on this page, is placed in the house or office of each subscriber, and is connected with the district office by telegraph wires. The signal box has a switch arm of three positions, as shown, respectively: "messenger," "police," and "fire." Each box has its own number, which is recorded at the district office against the name and address of the subscriber. In the interior of the box is a train of wheels, clock gearing, which, when the arm is turned, starts in motion, and the number of the box is given at the station, in the same manner as the fire-alarm box.

If a messenger is wanted, the switch is moved to "messenger," and instantly a trusty boy is sent to answer the call. Placing the switch arm to "police" brings a private policeman, and switching to "fire," brings the firemen, as afterwards explained. The basis of the system is, that the messenger, police or fireman's service shall be performed within three minutes, at any time of day or night. In such cities, where it is established, the employees of the company perform a great variety of public service.

The messengers run errands, carry parcels, make collections, tend offices, distribute handbills or cards and do about everything within the range of a boy's capacity. The companies are very careful in selecting boys and are responsible for their honesty, in a fixed sum. The business generally requires about one boy to each ten boxes and affords respectable employment to a great number of lads, who are, by strict discipline and business association, gradually trained to fill more important duties. In many cases people employ boys who are only needed for an hour perhaps each day; by this system many of these boys can be dispensed with, and at the same time they can find employment with the company.

The policemen are frequently called to remove obtrusive servants and other nuisances; and if burglars are heard in the house, or the occupants are alarmed by suspicious noises on the premises, a touch of the button brings assistance at any time of day or night.

In cases of fire the system is invaluable. Under the best system of city fire alarms it takes an average of ten minutes to reach a fire-alarm box, find the person in charge of the key and send in the alarm; and then the department must have time to reach the fire. With the district telegraph in the house the signal can be sent instantly and within three minutes firemen are working on the fire with extinguishers.

In this city a fire patrol has recently been organized by the Insurance companies, and arrangements have been made so that this patrol will respond to calls from any three district signal boxes. By turning the switch arm to "fire," a signal is conveyed to the central office. The operator then sends the alarm by telegraph to the fire patrol station, giving street and number, and the fire patrol with all the apparatus necessary to extinguish incipient fires and save property are soon on the ground.

At the same time the district office sends the alarm to the nearest engine-house, so that the steam fire engine will also come. In case the

fire gets too much headway word is sent by telegraph to the fire alarm office, and a general alarm is struck in the usual way. The company will have independent wires to each engine house in the district, so that no delay is necessary, as the gong will be struck as soon as a signal is made for "fire." It will be seen from this that the system is very simple and efficient in case of fire, as all this is accomplished by telegraph, and with as little fuss as possible. The patrol first comes to the house, and if more help is necessary then the nearest engine in the district, and then if the fire threatens to be destructive the whole department turns out. Usually independent firemen are kept by the fire companies, but the existence of the fire patrol here does away with the necessity of special policemen.

This telegraph company will, of course, have independent wires and gongs of its own. Still, if any one wishes to telegraph to any part of the world he can send the despatch by a mes-

District Telegraph Alarm Box.

senger, who is called to receive it, and need not move from his chair. The boy can also be instructed to wait for an answer, if desired.

The central office of this company is at No. 417 California street, in a room 25 by 75 feet. The first district will include a five-minute service from that center. Only one district has as yet been organized, and those on the outside limits of the district can get a message in five minutes. The boxes are being made in this city by the Electrical Construction and Maintenance company. The officers of the District Telegraph company are:—James Gamble, President; Geo. S. Ladd, Vice-president, and Stephen D. Field, Secretary and Treasurer. The rates to be charged are \$2.50 per month for use of boxes. Of course no charge will be made for putting boxes in and keeping them in order. The sum of 15 cents per half hour will be charged for the time actually employed by the boys. These boys are to be uniformed, and the policemen employed are specials.

This system is no experiment, having been tried with great success in other large cities. Here, only one district will be laid out for the present; but in time no doubt the whole city will be districted and then there will be a central office for each district. The advantages of the method are so obvious that they need no explanation after what has been already said. The tariff is not high and many business men will no doubt avail themselves of the facilities this offered them, at their offices as well as their homes. The messengers can be told to do anything that boys can do, and people are charged only for the time actually employed. The police system will do away with many special police, and the fire alarm is invaluable.

Students in the Field.

The first of a series of explorations, under the auspices of the University of California, is to be made during the coming spring recess, which began last Thursday. These explorations or surveys are designed to illustrate and teach in the field what is taught in the lecture-rooms at Berkeley, and will include geology and mineralogy, topography, surveying, zoology, botany and related studies. In conducting this out-door work the party will be under the usual discipline which is observed in governmental expeditions of the same general character. The objective point in this instance will be Mount Diablo and the country intervening between said place and Berkeley. In order to make the work more effective the number of the

Hydraulic Mining in California.

No. 18.

Distributor.

This is a strong cast-iron box, receiving directly from the supply-pipe all the water to be used by means of hydraulic machines in the mines. It is provided with two or more openings, to which the pipes, directly connected with the hydraulic nozzles, are attached. These openings can be closed by strong iron gates, raised or lowered by means of a screw. To change the water from one hydraulic nozzle to another the gate for the latter is opened by turning the screw. At this point two streams of equal power will issue from the two nozzles. Now, the screw of the first hydraulic nozzle is turned, the gate closes slowly, and the whole of the water is changed from one nozzle to the other.

These distributors are provided with as many as four gates, so that four hydraulic nozzles could be supplied from one of them, provided the supply of water and the feed-pipe were large enough to furnish the four nozzles at the same time. The distributor must be firmly fixed to the ground.

The Supply or Feed Pipe.

The size of this pipe must necessarily depend on the supply of water. In mines which use from 1,500 to 2,000 inches of water, feed-pipes of 22 inches diameter are generally used. When the supply of water is higher than that, and rises to 3,000 inches or more, it is advisable to use a pipe of 30 inches diameter, since the friction is lessened to a great extent by the large size.

The feed-pipe should descend from a strong bulk-head in as direct a line as possible, and with the least angles, to the mine. It should not be permitted to fall and rise again, unless this is unavoidable; and then it should be provided with an extra number of air-valves, with brass floats. (The depressed portion of the pipe would retain the water all the time, and might be at any moment the cause of a collapse, unless efficient air-valves could supply air quick enough to prevent a vacuum.) These air-valves ought to be provided with brass not wooden floats, since the swelling of the latter will, under some circumstances, wedge them so tightly in the valve that the atmospheric pressure is unable to remove them; a collapse is the consequence.)

The water at the bulk-head must cover the mouth of the pipe for a depth of 3 or 4 feet, to lessen the amount of air; some of which, under all circumstances, will enter with the water. Where the feed-pipe has a permanent position, it is the best plan to have joints riveted together; that part of the pipe which is liable to be shifted must be connected by hooks and wire, and the joints must be calked carefully. The pipe must be placed in such a position that it is immovable; on precipitous ground braces and frame-works, weighted down with stones, ought to be used at intervals. An air-pipe must be attached to the feed-pipe at or near its upper end. (See Fig. 1.)

The iron used for these feed-pipes varies from No. 16 to No. 11, and lower, according to the greater or less pressure; however, care should always be taken not only to employ the best charcoal-iron, but also to have it strong enough against all chances.

For a 22 inch pipe No. 16 iron was used for pressure up to 150 feet; No. 14 from 150 to 250 feet; No. 12 from 250 to 310 feet. For a 30-inch pipe No. 14 iron was used for pressure up to 150 feet; No. 12 from 150 to 275 feet.

The pipes supplying the hydraulic nozzle from the distributor will differ in size, say from 10 to 15 inches; must be made of No. 14 or No. 12 iron, and must be connected either by flanges or by hooks and wire; well calked and firmly secured in their position.

All the pipes should be protected by immersion in Dr. Angus Smith's preparation of coal-tar.

Fig. 1. A. Hook and Wire Connection; B. Flange.

party is limited, including some of the professors in the scientific colleges, and others selected according to their specialties in natural sciences.

When the party returns, the material collected and the field notes and general observations are to be properly worked up and a report will be made to the authorities of the University by the Secretary of the Association, F. A. McLean.

The expedition is under the charge of Prof. Jos. LeConte. The party is composed of the following persons in their specialties: In Natural Science, Prof. Jos. LeConte; Geology, Prof. W. B. Rising and F. State Jr.; Chemical Geology; A. W. Jackson, Jr., Mineralogy; F. P. McLean, Botany; John Sillman, Geology. The Engineering Department is under Prof. John LeConte, assisted by G. O. Edwards, L. L. Hawkin and E. A. Parker.

The above mentioned will probably be joined at the mountain by President Gilman, Prof. W. H. Brewer, of Yale, now lecturing at the University; Dr. A. Kellogg (creator of the museum of the California Academy of Sciences), and W. P. Gibbons, botanists, and Secretary R. E. C. Stearns in natural history. We shall give some account of the result of these explorations.

While speaking of the University, we may mention that Prof. D. C. Gilman has resigned the Presidency for the purpose of accepting a similar position in another university in the East. Prof. John LeConte, a member of the Faculty, has been appointed temporary President. While regrets are felt at Professor Gilman's departure, the appointment of Professor LeConte, who has been so long connected with the University, is a cause of congratulation.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

CORRESPONDENCE.

Mexican Mines.

The Native Silver District of Morelos, State of Chihuahua, Mexico.

(Written for the Press by A. E. Koels.)

[Continued from last week.]

Some distance to the northeast on the same side of the mountain, but on another spur, we find the

San Anastasio Mins.

With similar general direction, and about 18 degrees dip; also similar in point of general characteristics of the lode in point of matrix, nature of its ores, and signs of nearing such, although these latter contain more iron pyrites and more or less ruby silver. Like the San Gil lode, the San Anastasio shows an average width of three-fourths to one yard, in many places considerably widening out.

Discovered several years later than the San Gil by the same avila, its chlorides on the surface soon changed into native silver mixed ores, frequently becoming very massive and thick, so that the same had to be chiseled out, not breaking out by the blast.

The ownership passed in time into the hands of a very intelligent and energetic miner, Sr. Don Manuel Seenz, whose enterprise was soon rewarded by a large bonanza. Like all mines this also did not carry its metal in one continuous stretch, but rather in deposits more or less toward a certain direction—chimney-like; yet it has hardly ever failed to give sufficient low grade ores, of from \$50 to \$80 per ton, to cover the running expenses, and those very docile for amalgamation.

The silver is not coming out of the mine as bright and white as that of the San Gil; being more or less tainted by oxides, yet very pure, and gives considerably of the peculiar close called these black silver (*plata negra*) Pronstite which loses only 1 to 2 per cent. in smelting; also another interesting kind which looks like brightly polished steel.

Under the present administration of Sr. Don Angel Guerrero, the mina bids fair to give another great bonanza before long. In fact the barren spaces of the lode seem in no direction to be large, but need thorough prospecting.

The depth of the mine is 140 yards, and of its value speaks the large rubbish pile (*terrero*) whose silver contents are alone calculated to range over \$100,000.

A general working shaft, following the inclination of the vein down to the bottom of the mine allows the taking out of the rubbish by means of a windlass moved by mules. A great number of threads tend to enrich the lode, some of them carrying visible native silver on the surface. Four or five regular veins running with short distances parallel to the San Anastasio higher up on the slope, belonging to its claim have been but very little prospected, yet give all the most flattering promises and inducements for a tunnel enterprise which I understand will indeed be given at a later period. The mill driven by splendid, never-failing water power, is well appointed and of sufficient capacity.

The San Pedro.

About eighty yards west of the former, belongs to the Sáez heirs. Water having filled its lower works, which are said to be 120 yards deep, I did not inspect it thoroughly. The work in it has been stopped for over fifteen years. For a considerable time, however, it gave a great bonanza, a large part of which was in very massive native, especially "black silver." The water entering through fissures caused the stoppage of the workings; the last ones are reported to be in very good fourth-class ore, and public opinion states that very little work on them would bring the mine again into a bonanza. Its location is very favorable for tunnel enterprise, its general features resembling closely those of the San Anastasio.

To the southwest of the San Gil, higher up on the same side of the hill, lies the

Santa Matilda.

Consisting of two very formal lodes, lying in excellent mineral ground, about three-quarter yards wide, running southeast to northwest with a dip tending to unite them in about 100 yards depth. At the place and time of its discovery, some twenty years ago, it gave very rich chlorides and a considerable amount of first and second class native silver. A gallery driven by its present owner, Signor Don Ignacio Rocha, to a considerable length on the lower vein failed to give result; the upper one, called Cinco Señoras, promises, however, very fairly. The depth of the workings does not pass sixty yards. In most general features it resembles San Gil, giving also much ruby silver.

The geological formation of the mountain begins to change unfavorably a short distance west of the mins. The owner, I understand, is desirous to enter into acceptable arrangements with parties willing to work the mine in a regular way. It is very favorably spoken of by the mining population.

Going over to the west side of the mountain, we find on it, or on spurs running out from and hills separated from it by deep ravines,

quite a number of mines and veins, either entirely virgin yet, or at best but very little prospected far want of enterprise and capital, although some of them seem to offer very fair hopes of giving good results with comparatively little outlay.

The mineral ground throughout here is of the very best class, and those lodes which have at some time been opened, now, however, lying idle, have not disappointed the expectations their appearance caused in their owners. The most of these desire enterprising capitalists to take hold of them, and would offer fair conditions to a snob. Among such mines I only mention the El Carmén, Santo Nino, San Miguel, San Juan, La Consalacion, Los Hilos, Dulces Nombres, Bichares and Las Papas, all of which have been merely picked at, hardly any over ten to thirty yards in any direction.

The San Francisco.

Owned by Signor Don Gabriel Gomez, includes four or five formal veins, some of which gave very rich metallic silver. Their deepest work hardly reaches forty yards. So far as I have convinced myself, its prospects are very flattering.

La Trinidad.

Composed of two lodes running near together from southeast to northwest, with a west dip of 18 degrees, which have at various times produced fine deposits of very solid native silver and chlorides. The fourth class ores are reputed to be very rich in sulphurates, and the quality of the metal produced the richer the deeper developed. Considerable calcspar seems to enter the matrix of the lode, and all the distinctive features of this mine appear highly flattering. Its owner, Sr. Don Benito Diaz, not being able to work it properly for lack of funds, would wish to enter into negotiations about it on liberal terms. The work on the veins nowhere exceeds 45 yards in depth. West of the San Francisco is found the great

San Joaquin Mine.

At the time of its discovery in the first quarter of the century, so celebrated by its great bonanza, that from it dates the still existing small mining village San Joaquin de los Arrieros. No precise records are now existing as to its actual production, it is only known that it gave many millions, a great part of which in the very richest kind of native, and even large masses of perfectly solid silver. Don Juan Escudero, in his "Estadística del estado de Chihuahua," speaking of it says, that he personally was present on the 9th of May, 1826, when the owners caused a blast to be made in one of the works, to throw a part of the vein down, not over 1½ yards long, by 1½ wide and 1½ yards high, which resulted in over \$7,000 in silver, of which they sold to him one single piece in native silver, of 73 pounds weight, at the rate of \$16 per pound. The depth of the mine is not much over 100 yards, and wherever accessible, the large saloon-like cavities show plainly where the deposits of metal were taken out. The upper workings being partly filled up with rubbish, only the lower ones can be entered; where by later owners a short tunnel was run, resulting also in rich returns, yet for some reason, unknown to me, not followed up. In this latter work a very rich cross-vein, containing a great deal of iron, was cut.

The lode runs along the top of a very narrow spur from east to west, dipping south, and shows from ¾ to 1½ yards wide, with a good deal of calcspar in its matrix. The prevailing country rock is diorite. On both sides of the spur run also a number of other formal lodes parallel to the San Joaquin, all now included in one claim known as the

El Carmen.

Owned by an American, Mr. B. J. Jones and parties represented by him. Some of them have been opened and prospected to an insignificant extent, all have given rich chlorides and good deposits of native silver. Quite a number of good sized cross lodes traverse them from southwest to northeast in almost regular short distances, while many threads carry also metal in them. The Carmen vein is, however, the only one being worked at present with a small force, the means for larger exploration being wanting. It has never, from the surface down to its lowest workings, about 40 yards, failed to pay expenses, occasionally giving deposits of very rich native silver. Seldom, indeed, might a claim be found in any mining region which offers finer facilities for exploration by means of a tunnel than this one. Such a one, started at a point on the south side of the hill, would cut, in sufficient depth, all the principal veins in about 100 yards length, and more than likely soon open up a new bonanza. Right in front of the Carmen, a few hundred yards distant, crops out and mounts on another hill, an immense vein of quartz, called El Promontorio, from 6 to 9 yards wide, which it is said may be traced for many miles, and shows traces of silver, gold and copper, yet has never been opened sufficiently to prove its value, and is still without an owner. The mill pertaining to this Carmen mine, called Charcos, and provided with American machinery, lies about one hour's ride to the east of it on the Tenorihua river. Leaving this mine and passing further westward, a deep ravine known as La Corcoyada, we come to a mountain system which, cutting through the former one in a southwest direction, offers many striking peculiarities in its geological features, differing considerably from those which accompany the lodes already spoken of. Its principal class of rock is granite, with occasional

patches of syenite, greens'ane and diorite; also porphyry. Here lies the

El Socorro Mine.

A comparatively new one, first discovered about 15 years ago, by Don Juan Avila, who found rich chlorides cropping out in various spots, but was satisfied in taking out what there was on and near the surface, without caring to follow it up any deeper than four to six yards anywhere. Similarly to this worked at a later day Don Beaino Diaz, who took from a small shaft of five yards about \$4,000, a part of it in massive, sanorous silver.

Finally, about a year ago, the claim got into the hands of foreign gentlemen, partly residing in San Francisco, Cal., who determined to open it in a regular way, and are at present engaged in doing so, with very flattering prospects of being well compensated for their enterprise, although the depth of the works pass as yet in no place 30 feet.

Included in the same claim, about 400 yards to the northeast, on another spur of the same hill, runs

La Ascension

Vein, in a southeast to northwest direction, and somewhat parallel to the former, only opened so far by a shaft of about 11 yards, and a short gallery driven on a thread, 28 yards below. The prospects are similar to those in the Socorro; in both mines the workings must first reach a greater depth before more constant stretches of ore than those met with near the surface, may reasonably be expected.

Some seven yards south of the above shaft a very wide lode, never touched yet, crosses the Ascension from east to west, and between this end the Socorro various others crop out, likewise a number of threads, some of which carry native silver (white and black) even on their surface, and having, where picked at, given deposits of very solid metal. The expectation of a bonanza, or larger deposits, when they do strike the main vein in greater depth, seems therefore well justified.

The mineral country on this hill looks everywhere splendid; and more so still on the yet unexplored western portion of it, where all these lodes cross over to and others besides abound. The Socorro claim may therefore be looked upon as one of the most promising ones, if the granite formation should prove to favor the carrying of the native silver in equal rate with the diorite, in which they have heretofore been exclusively worked.

Besides these Mins

Already mentioned, there are yet, as I said before, a large number of such which hardly deserve that name, being rather mere holes and pickings on lodes; yet there can be no doubt that many of them would prove remunerative, if some capital should be spent upon them in a judicious way. Even if held at present by individuals, the most of this latter class could be acquired for a trifle.

Leaving now this native silver region, we find to the east of the town of Morelos, in a different geological formation, belonging under the same jurisdiction, in more or less distance from the center, a very large number of lodes, whose ores consist in argentiferous lead, fahl and copper ores, whose ley runs sometimes very high indeed.

Some of them, as for instance the mines of Zapote, were worked over a century ago, as the remains of large reduction works show, yet all knowledge of them has been lost. The same may be said of the old, abandoned mines of Loreto, to the north of Morelos, where the *gambuzinos* have extracted ores from some pillars and the rubbish piles that gave \$70 per ton. Very ancient mines we find to the west of Los Tajos, which have left very remarkable traces (even large cakes of very rich silver bullion in some of the tumbled-down furnaces) the mine of El Roserio, whose ore gives from \$300 to \$400 per ton, and to the southward the mines of La Higuera, with very rich fahl and copper ores.

In fact, wherever foot and eye turns to, we find the mountains full of rich metallic veins, yet neither enterprise nor capital to work them.

Australian Notes.

[From our Australian Correspondent.]

EDITORS PRESS:—The statistics in my first letter will have shown you that in Australasia, the colony of New South Wales is second in importance to Victoria only, and the head of its recent government has frequently declared his intention of placing it in its original position as the principal colony of the group by wise and judicious legislation, his opinion being that the protective proclivities of the people of Victoria will throw them behind in the race. However this may be it is quite certain that there is ample material for the fulfillment of his intention. The area of that colony being nearly four times as great as that of Victoria, and most of it of a valuable character. Large tracts of it make admirable pasturage. Equally large tracts are especially suitable for agricultural purposes, whilst minerals of all kinds abound from gold to iron, and from splendid coal to poor oil shale. Its climate, too, is salubrious, especially on the eastern coast, the delightful sea breezes from which, come up every afternoon after the hottest day. On this coast at the head of a magnificent harbor is its capital city, Sydney. Of the city itself I cannot speak very highly as its streets are for the

most part comparatively narrow and crooked. The houses, however, bear a more substantial appearance than those at Melbourne, being built of a free-tone which abounds in the vicinity, instead of the woad which is to be still found in the older and poorer buildings of the latter city.

The pastoral interest at present predominates, there being according to the latest statistics no fewer than 328,014 horses in that colony, besides 2,710,374 cattle, 19,228,590 sheep and 238,342 pigs, whilst there are only about 300,000 acres under cereal crops, and 155,000 acres under hay, potatoes, vines, etc. This, in conjunction with the gold, tin, and coal mining interests indicates a large amount of material prosperity for a population of but little over half a million.

The most exciting event in this colony since my last letter has been the downfall of one of the most popular governments that ever held office, and the unusual course pursued by the Governor afterwards—matters which have, I presume, no interest for your readers except to know that it has all taken place over the release of a notorious hushhanger named Gerdiner. The Governor, it appears, pardoned this murderous cutthroat on his own mere motion, on condition that he left the colony to pursue his pleasant avocation elsewhere. Against this proceeding the neighboring colonies, as well as a large section of the people of New South Wales, raised their voice, but in vain; and the Governor now has the chagrin to find his conduct publicly condemned by the colonial parliament, and obliged to send forth a mover of the hostile resolution to form a government.

Since last I wrote, a machine for reaping, gathering and binding has been patented in Victoria, the most noticeable feature in which is the automatic binding of the sheaf with string or cord. One end of the string is sown to a narrow strip of canvas (which the inventor calls a pad), and then straitened across the entrance of a sheaf box. The cut grain is then forced against the string into the box, and when full the other end of the band is sown to the pad, which is cut off the end of the canvas strip and the sheaf is allowed to fall gently on to the ground. The machine has not yet been tried in the field, but the inventor, a Mr. Thos. Harvey, of Preston, expresses himself as being confident of its success. When it is tried, I will let you know the result. E. W.

Melbourne, Feb. 8th.

Montana Mines—Miners Wanted More than Capitalists.

EDITORS PRESS:—The general topic of conversation in this section is concentrators, mills, smelters, and the long expected coming of those capitalists who are to pay immense sums of money for locations, and put up the necessary works for the reduction of the ores in the big bonanza. I believe our territorial papers, or at least the majority of them, Montana contains more wealth than any other Territory or State on the continent, and everything is going ahead ship-shape. About all the mines are showing well, rich ore is plenty and has been, the different companies all have very able superintendents, old and experienced miners. All the works for the reduction of ores are a perfect success, and nearly all are in the charge of Judge so-and-so, or Captain somebody, or Colonel somebody else (and by the way it is astonishing what a large number of those worthies emigrated to Montana); but, strange to say, the billion product don't tally with the accounts, and those capitalists seem to think there is a screw loose somewhere.

My opinion is that our papers unintentionally do the country great harm by publishing such glowing accounts. Outside capitalists would naturally suppose that experienced men, like those generally mentioned, working rich ore, would certainly make a better showing than has been made, they therefore conclude that the lodes are not what they are represented to be. I think Montana is more in want of miners than anything else.

The next success made by any mill or smelter as near as I can learn has been by a little four-stamp mill on the Big Prickly Pear. It started up under new management last spring; it was generally expected to do wonders. I went to see the proprietor in regard to the working of some ore, he said that he would not work anything but free milling ore, and that he would work none unless it would assay \$100 per ton, and in fact, he did not wish to work any unless it went \$150 per ton. A few bricks were turned out from this establishment during the summer, and it was forthwith proclaimed a grand success. Smelter after smelter has been built, but shortly closed down for repairs, but failed to start again, as the large number of ruins in the neighborhood of Jefferson City, Belleville and Clancy Creek attest, and the sad fate of the big Helena smelter.

When our people come to the conclusion to do more work, and talk less, things will change for the better (I don't mean a drive at everybody for there are exceptions), something will be developed worth the attention of capitalists, for I have good faith in the value of the mines.

Now, unquestionably, if our concentrator is put up that will concentrate, others will follow, and a new era will be entailed, for from as reliable information as can be gained and personal knowledge there is a large number of lodes that show quite large quantities of low grade ore near the surface. The work that has been done can only be classed as surface work.

SEABRO.

Unionville, Montana, Feb. 19th, 1875.

SCIENTIFIC PROGRESS.

What are Bacteria?

The great question of the origin of life seems to depend on the answer to the above question. Four answers, says the *Scientific American*, have been given to this question: Ehrenberg's, that they are animal organisms of the lowest grade having an individuality of their own; Hallier's, that they are of the nature of spores, produced from and destined to develop into some of the simpler microscopic fungi; Cohn's, that they represent the free-swimming stage in the existence of certain algae; Bastian's, that they are the first and most common developmental phase of newly evolved living matter, capable, either singly or in combination, of developing into many different kinds of living things.

Ehrenberg's view is quite obsolete. They are not animals, nor are all agreed that they are vegetables. For these and other doubtful organisms of the lowest rank, Haeckel has proposed a new kingdom—the *protista*, intermediate between connecting the animal and vegetable kingdoms, and from the modification of which both animals and plants have been derived. Barring the last clause, the proposition bids fair to be generally adopted, as it relates to a sort of no-man's land—a group of organisms in which animal and vegetable characteristics are so united that they cannot be classed with either animals or vegetables.

All that is positively known of the origin of these organisms is that they speedily make their appearance in all infusions of organic substances exposed to light and air, and under other conditions not so clearly understood. The smallest—usually globular—specks, ranging between a one-hundredth-thousandth and a one-twenty-thousandth of an inch in diameter, have been variously denominated monads, microzymes, and plastid particles. According to Bastian, who adopts the last name, they are merely temporary and initial forms of many organizations which may afterward present distinct characteristics of their own; though some of them, through default of necessary conditions, may never actually develop into higher modes of being. From those which do continue their development, he holds, bacteria and other forms, which others have thought specific, are produced by a direct process of growth and development. In size and character, these bacteria and others differ according to the degree of putrescibility of the solution in which they appear, the amount of heat to which it has been exposed and other modifying conditions. From this point of view a rigid specific classification is uncalled for and impossible.

According to Hallier's view the smallest living specks of living matter—he calls them micrococci—are minute particles of plasma or naked matter, produced by the repeated subdivision of the nuclei of fungus spores, or by the breaking up of the protoplasmic contents of the larger reproductive cells of certain fungi. When introduced into a fluid capable of undergoing alcoholic fermentation, these micrococci, he says, develop into cryptococci, bodies resembling ordinary yeast cells; in an acid fluid, or one which becomes acid through fermentation, the micrococci assume the elongated forms commonly called bacteria, but which he calls anthrocoeci. The first and the last named multiply by fission, while the cryptococci increase by a process of budding. By an elongated growth the anthrocoeci are described as developing into distinct fungi of the oidium type.

Thus, determined by the nature of the fluid in which they grow, micrococci are said to develop either at once into *torula* cells, from which a perfect fungus may result, or into *bacteria*, which develop into segmented filaments, and then into distinct fungi of a different type. The various fungi so developed are supposed by Hallier to be capable of reproducing micrococci, as already described, and so completing the circle of life; an hypothesis which seems to have no other foundation than a desire to escape the necessity of admitting the origin of micrococci *de novo*.

These minute organisms are thought by many to be the cause of those contagious diseases which are "endemic," or peculiar to peoples or locations. Whether they are really responsible for the various maladies attributed to them is a question which involves too many considerations to be discussed in this connection.

SULPHUR AS A FIRE EXTINGUISHER.—M. Teller suggests the use of sulphur as a means of extinguishing fire on board ship. The material when burning in the air, as is well known, generates sulphurous acid, in which flame is not sustained. M. Teller proposes to cover wicks with the sulphur, and to let them down into the burning portion of the vessel through holes in the deck. Sixty-six pounds of sulphur ignited will entirely absorb the oxygen in 3,360 cubic feet of air; but as only half the oxygen need be removed in order to render the atmosphere unfit to support the combustion, thirty-three pounds are sufficient for the volume mentioned.

NATURE is the only workman to whom no material is worthless, the only chemist in whose laboratory there are no waste products, and the only artist whose compositions are infinitely varied, and whose fertility of invention is inexhaustible.

THE WISDOM OF THE EGYPTIANS.—Philologists, astronomers, chemists, painters, architects, and physicians must return to Egypt to learn the origin of writing—a knowledge of the calendar and the solar motion—of the art of cutting granite with a copper chisel, and of giving elasticity to a copper sword—of making glass of the variegated hues of the rainbow—of moving single blocks of polished granite 900 tons in weight, for any distance by land or water—of building arches round and pointed, with masonic precision unsurpassed at the present day, and antedated by two thousand years to the Cloaca Magna of Rome—of sculpturing a Doric column one thousand years before the Dorians are known in history—of fresco painting in imperishable colors—and of practical knowledge in masonry. And it is no less clear that every craftsman can behold on Egyptian monuments the progress of his art four thousand years ago, whether it be a wheelwright building his chariot, a shoemaker drawing his twine, a leather-cutter using that selfsame form of knife which is considered the best form now, or a weaver throwing the same hand shuttle.

A New Re-Action of Essence of Mint.

Dr. Roncher has observed that when essence of mint is added to twenty times its weight of acetic acid, and the two agitated, a blue coloration gradually increasing in intensity begins to develop in about half an hour. As the color deepens, a very marked dichroism is noticed, the liquid appearing pure blue by transmitted light, and a beautiful cinnabar red color by reflected light. This appearance is comparable to that of alcoholic solutions of certain aniline compounds.

The coloration thus produced is not permanent. Under the influence of light it changes first to green, afterwards to yellow. The addition of water is followed by the separation of a very pale blue scintillating liquid. On filtering, part of the blue coloring matter remains on the paper; this speedily changes to red, and is finally decolorized by the air. Caustic potash causes instant decolorization.

The essence of mint employed was that usually met with in commerce. Dr. Roncher has examined other essences of known and diverse origin with a view to ascertain if they reacted in the same manner and to the same degree. He found that pure menthol dissolved in acetic acid without production of color. Essence of turpentine, camphor and essence of citron do not give rise to this appearance. —*Chemist and Druggist*.

OXYGEN IN HYDROGEN.—Hydrogen gas, whether prepared by electrolysis, or by the decomposition of water with the aid of zinc and sulphuric acid, contains an appreciable amount of oxygen. In fact, it would appear that it is almost impossible to free it entirely from this admixture, such is the eagerness with which hydrogen seizes upon oxygen, whether atmospheric or contained in solution in water. No definite compound is formed, but simply a mechanical mixture, in which the properties of both constituents remain unmasked. Professor Grove first noticed this peculiar property of hydrogen while experimenting on the contraction sustained by different gases after ignition and subsequent cooling. He found that the contraction, in the case of hydrogen, sometimes amounted to one-tenth of the original volume. He found, on examination, that this was due to the oxygen held in suspension by the hydrogen, and which the latter obtained by passing through water.

NEW MICROSCOPIC TELESCOPE.—Mr. C. B. Boyle recently exhibited before the photographic section of the American Institute, in this city, a new optical instrument, which he called the microscopic telescope. It consisted of two parallel telescopes, about three feet in length and two inches in aperture, connected with hinges and separated to the distance of the eyes by an adjusting screw. In order to produce the effect of the microscope, he places before the object glass prismatic lenses of about three feet focus, so that when these lenses are in position, an object three feet in front of the object glass will be seen with both eyes distinctly, and magnified according to the power of the eye piece.

AN EXPERIMENT WITH SILVER.—Böttger offers the following experiment to show the formation of binoxide of silver and metallic silver by electrolysis. A concentrated solution of nitrate of silver is put in a wide glass cylinder, and two platinum wires, forming the poles of a galvanic battery, are placed in the solution in a vertical position, about three inches apart. Beneath the anode is placed a small watch-glass, and the current from two Bunsen cells started. In a few minutes brilliant needles of binoxide of silver appear on the anode, and becoming too heavy to remain unsupported, fall on the watch-glass beneath. On the cathode an equivalent quantity of pure metallic silver collects in snow-white dendritic ramifications.

CLOUD OBSERVATIONS.—The Signal Service observer, on the summit of Pike's Peak reports that the local storms there experienced originated over the parks to the westward on hot afternoons. On one occasion he was favored with an excellent view of the exterior structure of the clouds of a tornado, when he observed that while the cloud-bearing currents of air float toward the center they had a decided downward movement, but that masses of smoke-like vapor rapidly ascended through the interior funnel.

MECHANICAL PROGRESS.

Aluminum—Its Use and Preparation.

It is now about seventeen years since Deville first produced aluminum on a commercial scale; but thus far the cost and not the lack of desirable qualities seems to have prevented it from obtaining any very extensive application to useful purposes. The cost of its preparation, however, has been gradually reduced, until there is now a reasonable expectation that it will soon be placed at so moderate a price as to greatly increase the demand for it.

It Possesses Many Advantages

Over brass, silver, nickel and steel, and combines all their qualities without their objectionable weight, and a simple statement of its various recommendations to instrument makers will be all that is needed to make it known as theoretically the metal for the purpose.

Its lustre is bluish white.

It is non-magnetic and therefore will not deflect a needle by its presence.

It can be electro-deposited.

It neither rusts nor tarnishes so readily as brass, unless when in very thin sheets.

It is not acted upon by the air or water at common temperatures, damp air slowly tarnishing it. When intensely heated in a current of air it suffers only slight oxidation, heated to redness in an atmosphere of steam it slowly oxidizes.

It is readily acted upon by hydrochloric acid which evolves hydrogen and forms chloride of aluminum. Sulphuric and nitric acids do not affect it at common temperatures, but when boiled in the latter oxidizes as long as heat is maintained. Boiling in acetic acid does not affect it. Concentrated alkaline solutions slowly oxidize it and hydrogen is liberated. It is not affected by sulphur or sulphuretted hydrogen, or by solution of the alkaline sulphides.

The alloys with other metals are too brittle to be made use of for the purpose of this article.

Atomic weight 27.5; specific gravity 2.67 when rolled, when cast, 2.56.

It is more malleable than tin, platinum, lead, zinc or iron, being next to copper, and less malleable than gold or silver.

Next to copper it is more ductile than zinc, tin and lead, and less ductile than gold, silver, iron and platinum. Its fusibility is at a point little less than that of silver.

It can be worked into any shape, and there are no deleterious effects arising from working in it, or using it when manufactured into vessels for cooking purposes.

We are conversant with facts of poisoning by cooking vessels made of copper, by glazings containing lead, and the formation of verdigris on spoons of alloyed silver; but if people were only determined to produce these utensils from aluminum, all danger from poisoning would be removed, and we would have vessels, the appearance and durability of which would leave scarcely anything to desire. They would be more convenient to handle than our light crockery ware, for they can be made as light, and what is important, cannot be broken.

Splendid pitchers, plates, lamps, goblets, etc., might be manufactured from deaened and embossed aluminum; and the lightness of spoons of this metal would make them more convenient than those of silver now in use. In this case it is not the price, but only prejudice, which presents itself as a drawback, for the price is only half of that of good silver; besides, the difference in the specific weight of both metals and the consequent cheapness in the use of aluminum are so great that, for the value of one silver spoon, at least seven equally large aluminum spoons might be bought.

True, aluminum is neither a rare nor a noble metal, but it possesses, nevertheless, advantages over alloyed silver which gives it a much finer appearance; it does not get black, nor does it form verdigris, and what it lacks in brilliancy and appearance is well compensated for in its agreeable lightness. But, unfortunately, it has been found impossible to plate aluminum, either by the electro-galvanic or the foil method.

It is largely manufactured in England and France, there being a large factory at Newcastle. New methods are being discovered for obtaining it from kaolin or clay, inexpensively, and considering that it combines the ductility and malleability of copper, with vastly more than the strength of steel (it is placed by some as thirteen times stronger) with the lightness of chalk, it certainly should take the place of metals less adapted to purposes where strength, lightness and bulk are desiderata, as is indisputably the case in the manufacture of fine instruments for engineering field use, where weight is an objection and increased size within certain limits desirable.

The ordinary transit, weighing eleven pounds, may be made of aluminum to weigh three pounds without decreasing its size or increasing its cost, or the arcs may be made five times as large under the same weight.

The latest new phase in its manufacture is that employed by Gernesi, of London, who prepares this metal by placing a mixture of 100 parts of alumina, obtained in the usual way from kaolin, etc., with 40 parts of charcoal, heated to redness, in retorts at a dark red heat, and leading chlorine into them from

an iron gasometer lined with lead, and closed with gas tar covered with hydrochloric acid. The volatilized chloride of aluminum formed is condensed in vessels of sheet iron, glazed internally, and is decomposed by an electrical current produced by a magneto-electric machine. The liberated chloride is returned to the gasometer.

The present cost of aluminum is a little less than one-half that of silver.

To Form Perfect Squares.

Squares can be tested with the dividers by drawing two circles, one within the other, from the same center, of 16 and 12 inches diameter respectively; then set the dividers to 10 inches, insert one point in any part of the outer circle, and mark the point exactly where a circle (drawn with the dividers in this position) would intersect the inner circle; now draw a straight line through the center of the circles and through the point marked in the inner circle; and through the outer one, another line starting from the point where the dividers were inserted in the outer circle through the center of the circles, until the outer circle is reached. If this is done exactly, the points where these lines intersect the outer circle will form the corners of a perfect square whose side is 11.337 inches. If the square is correct, it will fit the square thus formed and also the lines in the center, which divide the circle into four equal parts, and the angles must be 90 degrees. This is based on the rule for finding the hypotenuse of a right angled triangle, thus 6 square=36 and 8 square=64, sum 100, the square root of which is 10. This is sometimes called the 6, 8 and 10 rule for squaring buildings.—*Ex.*

IRON AND ITS USES IN BUILDING.—The use of iron as a building material has, of late years, increased so rapidly, especially in works of magnitude and importance, in consequence of the many facilities and plans by which it can be manufactured into almost any required form, and the almost unlimited strength it possesses if wisely treated and properly applied. Yet, notwithstanding the enormous amount of iron construction that architects see constantly employed in all directions by engineers, it would appear that very few of them deem it worth while to learn much about its capabilities, usefulness and qualities as a building material. Architects occasionally use iron in columns and girders, but they make but little effort to extend its use so that it might take the place of such material as have been used from time immemorial, and with which they are better acquainted, such as brick, stone or wood. Whenever any very large building is erected, the whole credit of the design and execution is carried off by an engineer, although perhaps an architect may be called in to assist in the decorative features. This state of things will continue so long as architects are contented to take all their knowledge of iron construction at second hand from the engineers. It is, however, a matter of serious consideration whether the architectural profession should be satisfied by simply endeavoring to imitate the styles and modes of building employed in former ages, rather than attempt to keep up with the rapid advance of the present age, and meet its requirements by adopting the use of a material of which our ancestors had but very limited knowledge.—*Ex.*

DISTRIBUTION OF STEAM.—M. A. Van Waeyenbergh has invented a new arrangement for preventing the dangerous irregularities which occur in steam cylinders; he adopts two or more escapes and sets of slides, placed on different sides of the cylinder, and so arranged that they are all connected with the extremity of the cylinder by the same passage. He admits the steam and governs its introduction directly by the regulator according to the work to be done. With this object the arbor of the levers which command the valve slides forms part of a sliding sector which is furnished with clickwork, rendering it at any determined moment independent of the slides and transmission rods. When this occurs, the steamway, which was open, closes instantaneously, and the inlet being suppressed, the steam acts by expansion in the cylinder until the piston has reached the end of its stroke. The discharge port then opens and the steam passes into another cylinder, into the condenser, or into the air, according to the circumstances of the case.—*London Engineering Times*.

CONDENSATION IN STEAM CYLINDERS.—By the use of lead facings to pistons and cylinder lids, a considerable economy in the use of steam may be effected. An iron lid and piston will, other things being equal, condense more than three times as much steam as a lead faced piston and lid. The thickness of metal heated and cooled at each stroke is not considerable, and not far into the metal a zone of constant temperature, lower than that of steam, will be found. The distance from the zone to the inside of the cylinder will depend upon the conducting power of the metal, and will be about 9 for lead to 12 for iron. It may be shown that, in any case, the thickness of lead facing may be kept within very moderate limits. Other materials may be used for the same purpose, as for instance, tin, the specific heat of which is 0.562, its specific weight being less than that of iron. Its conducting power, however, is in excess of that of iron, being as 15 to 12.—*Engineer*.

A SALT LAKE mechanic is perfecting a fast printing machine, which he claims will surpass in speed any press yet invented, and work a revolution in the printing business.

Industrial Items.

ABOUT two years ago a steamer was constructed at Stockton for Russian merchants doing business at Nicolaefski, who desired her for use on the Amoor river. The steamer gave such satisfaction that orders for two more steamers of the stern wheel style were received by her builders. The new steamers have been built in sections for convenience in transportation. Each is 135 feet long, 70 feet beam and 5 feet depth of hold.

MARBLE from the Tuolumne quarries is attracting considerable attention. A Stockton paper mentions having seen four large slabs at the depot there a few days since, which weighed about ten tons, en route to San Francisco. The quality of the marble seemed as pure white as the Venetian, with a small speck or fluke of black throughout.

A CORRESPONDENT of the *Tulare Times* advocates the building of a canal for irrigation and transportation on the west side of the San Joaquin river, and furthermore that it should be done at the expense of and owned and controlled by the State, or if that is not feasible then incorporate a company and seek State or National aid.

SHIP building on the Pacific Coast promises to take a new impetus from this recent action of the Board of Underwriters, who propose to rate vessels built of Puget Sound fir, under certain specifications, as A. 1. The specifications in detail are being prepared, and will be made public in a few days.

Of the exports from San Diego during the past year we note, from the report of the President of Chamber of Commerce, the following: wool, 1,000,000 lbs., honey, 400,000 lbs., wheat (raised), 200,000 lbs., of which latter product the first cargo was recently shipped direct to Europe.

Two French gentlemen, from San Francisco, have been examining a large tract of land above the junction of the Gila and Colorado rivers, with a view of settling a French colony thereon. They expect 100 families to arrive soon and make a commencement.

Four coal banks are in operation near Empire City. Each mine employs about 75 men. Fifty tons are daily taken out of each mine. The coal is extensive and of good quality; most of it is shipped to San Francisco.

THE two foundries and two planing mills in Santa Cruz are busy turning out machinery and doing work for the two railroads now being constructed into town.

THE *Lukenport Bee* says: "Such is the increase of our incoming population that it is utterly out of the question to find a dwelling to rent."

THE *Stockton Independent* urges the erection of suitable buildings for storing, and the establishment of a wool-grading institution in that city.

THEY are at work upon a number of threshing machine engine at the Vallejo foundry.

MR. DALTON, of Pacheco, intends moving his foundry to Oakland.

THREE good sized sailing vessels will be built at Coos Bay this season.

A grist mill is being erected at Westminster, Los Angeles county.

A NEW saw mill has been started in Tehachepi.

Sales at the S. F. Stock Exchange.

flasks, and the clean-up of this week will give at least twenty-five. Ores have been found along the entire length of the claim—3,200 ft—and it is said by mining experts to be one of the richest and largest mines in the State. The Buckeye is not turning out as much as the Abbott, but it is a good mine. There are other mines in the neighborhood that would have been worked this spring, had the price of quicksilver remained where it was six weeks ago; but the bottom has seemed to drop out of the market, and there will be but little work done on new mines.

EL DORADO.

FINE YIELD.—*Mountain Democrat*, March 20: Gross has made a run at his quartz mill on Big Canyon. It is a five-stamp mill and requires but one man to attend. It crushes six tons per day of twenty-four hours. Their late run consisted of twenty-five tons. It yielded within a small fraction of \$2,000, or \$80 per ton. Not had for a beginning, certainly.

INYO.

RAPID PROGRESS.—*Panamint News*, March 18: The work on the S. V. M. & W. Co.'s 20-stamp mill is progressing very rapidly. The frame for the boiler and engine room, which is built from the best of sawed timbers banded here from Spadra is already erected, and carpenters are now putting on the siding. Capt. Bell has a good force of men at work, and he thinks in four weeks time he can have all the buildings completed and a large portion of the machinery in position. He has sent for more carpenters and millwrights to hurry the work along. Good mechanics can find employment for some time to come at good wages—\$6 a day. There will not be any demand for men on the mines until the mill is about completed, as the company have already a large amount of ore on their dumps.

NAPA.

OAT HILL DISTRICT.—*St. Helena Star*, March 18: We hear very favorable accounts from the mining claims situated in the Oat Hill mining district, being a little north of the Phoenix mine, and judging from the information we received are sure that some of them are certain to become very valuable shortly. The Mercury, owned by Roberts & Co., still keeps up its reputation as one of the best claims in the district; as an evidence of the richness of the ore extracted from this mine, we are assured on good authority that one man with three quicksilver flasks for reducing apparatus, has extracted one hundred and fifty-five pounds of quicksilver during the last two weeks; they are putting up a small retort and expect to commence reducing during the present week. They have plenty of metal on hand, and plenty more in sight in all their workings. The Enreka company are hard at work developing their property, they have fifteen or twenty tons of good ore on hand and have good metal showing in four of their workings; they propose commencing to reduce their ore shortly, but at present are running a tunnel to cut a seam discovered in their upper workings; they have already run about 100 ft and have found encouraging indications of the proximity of a large body of metals as in the bottom of their tunnel; they cut what appeared to be the crown of the ledge twelve ft in width, every inch of which was good paying ore. The Berryessa company are running a tunnel to tap their ledge, and from time to time cut through small seams or stringers of exceedingly rich ore. The Edna Mabel Consolidated, Oak Knoll, Oceola and several other companies are hard at work with encouraging prospects of reaping a rich reward for their labors.

NEVADA.

WHEEL BETSEY.—*Foothill Tidings*, March 20: This mine is being steadily worked, six men making good progress in the shaft, now down over 100 ft. The hoisting machinery has been at work some time and the pump will be started as soon as the shaft gets below the old drain tunnel. The present owners of Wheel Betsey, under Superintendent Smith, seem determined to retrieve her ancient reputation as a paying mine.

THE GOLD TRAP.—*Nevada Transcript*, March 23: We yesterday saw a ball of amalgam taken from the "gold trap" which has been in operation at the Gold Tunnel mine for the past week or more, and the size of it proves the amount of gold that annually goes to waste, notwithstanding the improved machinery in use. The owner of the trap will also put one up on the flume of the Manzanita mine, and demonstrate the amount that escapes there. We shall, the next time a clean up is made on the trap, give the particulars. From the present clean up it is impossible to tell exactly what has been accomplished, because the whole machine had to become charged, and the amalgam consequently had more or less copper in it. The next time something definite can be given. Enough is already shown to prove that gold is wasted with present machinery, and that the "gold trap" will save it if used.

PITTSBURG MINE.—We learn from Treasurer Sanford that the Pittsburg mine, located at Deadman's Flat, is looking splendidly. New hoisting works have been erected and are now in operation. The shaft is now 104 feet deep. The ledge in the bottom of the drift is three feet wide. Ten loads of quartz were crashed about a week ago at Larimer's mill, which paid \$63 in free gold, and there was a ton of sulphurets saved, which is supposed to be worth \$140 to \$170. The mine has paid all the labor expended upon it by way of development, and has paid dividends regularly besides. The mine is owned by the Cook brothers and E. P. Sanford.

SANTA CRUZ.

QUICKSILVER.—*Santa Cruz Sentinel*, March 20: Santa Cruz and San Lorenzo Quicksilver Mining Co., located in San Benito and Merced counties have bonded their mine to J. H. Remell of San Francisco for one year, for the sum of \$30,000, to develop the mine. As over two-thirds of the stock of those mines is owned in Santa Cruz, it brings a handsome little capital into our midst, and there can certainly be no longer a plea here of a scarcity of money or hard times. We shall have miners in our midst instead of wideawake energetic business men, especially if we hear many more complaints about the indifference to and want of public spirit in those who are able to assist every good word and work towards the advancement of the city and county in needed improvements.

SONOMA.

MINTO TREMS.—*Russian River Flag*, March 18th: The Abe Lincoln silver mine, eight miles northwest of Healdsburg, is applying for a patent.

The Yosemite, owned by John F. Grater and John Collins, located near Collins' store in Alexander valley, is now being worked. The surface croppings are good. The tunnel has advanced 50 ft.

The new furnace for the American works well. The Annie Belcher furnace is now reducing ore from the Socrates.

The Quaker tunnel near Pine Flat is now in to a depth of 110 ft. Silver ore continues to be found, and the prospects of the mine are good. The Geyser furnace is kept running steadily, yielding from 10 to 12 flasks a week. About 50 men are employed.

A 30-ton furnace will be erected as speedily as possible by the Mercury company, near Mercurville.

Stuart & Elder have sold all their interest in the Goyer.

In Guerneville District, the Great Eastern is looking very well. It has 30 men at work on the three main tunnels. At least 400 tons of ore are on the dump. Parrott & Co. will ship the Walbridge furnace material back to San Francisco and will speedily erect a furnace of another pattern.

The Mt. Jackson is also looking very well. Fifteen men employed. The lower main tunnel is 200 ft. long. From it an east drift extends 75 ft., about 40 running through good milling ore.

Mr. Canan spent a portion of this week at the New Almaden mines, with a view to the improvement of the furnace of the company over which he presides.

The Cloverdale mine shipped 18 flasks of mercury last week.

SAN BENITO

NEW MINE.—The genial face of E. C. Tully has not been seen at his office for several days past. We learn that the honorable gentleman has, in connection with Mr. Cody, been working with great success upon a quicksilver lode discovered near Tully's home, in Bitter Water valley. A small furnace has been placed upon the ground, and quicksilver worth \$1,000 a week is being distilled and shipped to market. If this yield continues Hollister will lose a lawyer.

TUOLUMNE.

STAA MINE.—*Tuolumne Independent*, March 20: This mine, owned by Jones & Woodman, located in American Camp district, above Columbia, is considered by an old and experienced quartz miner, who has recently examined the mine thoroughly, to be "the best show for opening a big mine in the county." They are now done 200 feet from the surface, (being 70 feet deeper than the old working,) and have cut into the vein 6 1/2 feet, and are not through it yet. A sample of rock from this spot, sent below for assay, goes \$1295 29 per ton, and a piece of rock from the same place, which we have in our office, assays \$2,000 per ton. This is supposed to be a spur of the main or mother vein, which crops out some 60 feet further up the mountain, and which, traced for 200 feet, prospects well the entire distance. In one place, five or six feet down, it shows a width of five feet, with appearance of increasing. At this point rock sent below for assay returns \$993.34 per ton, and at a point 200 feet distant croppings show an assay of \$59.19 per ton.

YOLO.

MINTO.—*Yolo Mail*, March 20: The mining excitement in the Coast range in Yolo county still keeps up, and since we have interviewed some of the principal leaders in the matter, we begin to believe that they at least are firmly convinced that they have discovered something rich. They are satisfied, at all events, and are about organizing companies to work the mines. Good indications of quicksilver, silver and iron are found, and many tolerably rich specimens have been exhibited. Should the mines prove fruitful in Capay valley; it will only add to the many other inducements to prompt the managers of the narrow-gauge railroad to hurry up.

Nevada.

WASHOE DISTRICT.

OPHIA.—*Gold Hill News*, March 18th: Daily yield, 150 tons of ore. The ore stops on the 1300 and 1465-ft levels, are looking splendid. The ore-house is full, and the ore is being piled up for future use at the mills, it being impossible to obtain a sufficient amount of milling capacity to consume the supply as fast as it is extracted from the mine. The north drift, on the 1465-ft level, shows a marked improvement during the last few days. The northeast drift, from the 1600-ft station of the north winze, is in 47 ft, the entire distance in rich ore.

CALIFORNIA.—Cross-cut No. 2, east, on the 1500-ft level, is again being steadily driven ahead, the face in excellent ore. The north drift from this cross-cut to connect with cross-cut No. 3, is being steadily advanced, the face in rich ore. It is now in 50 feet. The face of cross-cut No. 3, east, on the 1500-ft level, is still in fair grade ore. Cross-cut No. 4, on the same level, is steadily advancing toward the ledge, the face in very encouraging vein matter.

CONSOLIDATED VIRGINIA.—Daily yield, 450 tons of ore, keeping the mills running up to their full working capacity. The returns from the mills up to the present time indicate a yield of about \$200,000 more than that of last month, which will make up the returns of the present month upwards of \$1,400,000. The ore stops throughout the entire mine are yielding well, and show no signs whatever of giving out.

SERRA NEVADA.—Sinking the old shaft is making better progress, the rock in the bottom being firmer and blasting much better. The old drifts on the 700-ft level of the old shaft have been cleaned out and repaired and a northeast drift started to prospect the ledge and connect with the new shaft.

SOUTH COMSTOCK.—The new shaft is now down a little over 100 ft. The ground works well, water does not interfere, and the indications are that the ledge is not far distant.

WELLS FAROO.—Work being pushed ahead vigorously day and night, with three eight-hour shifts of men. The bottom of the shaft is now in porphyry and quartz, and the steam hoisting works are of sufficient power to sink to a depth of 1000 ft or more.

LADY BRYAN.—The west drift, at the 380-ft level, has struck a solid body of quartz and low grade ore, spots of which give very encouraging assays. The south drift, on the 80-ft level, is in 50 ft, the face still in ore that assays from \$80 to \$90 per ton. Sinking a winze on this ore body is commenced, the bottom of which is in ore of increasing richness.

NIAGARA.—The ore body at the bottom of the main incline is showing stronger and better as greater depth is attained. Machinery for the erection of new and first-class hoisting works, capable of working the mine to a depth of 1200 ft, is now on the way from San Francisco.

SENATOR.—Still driving the main north and south drifts on the 400-ft level vigorously ahead. The south drift has developed a vein of darkly stained quartz, two feet in width, of a very favorable character. Assays from this vein shows gold and silver both in encouraging quantities.

BELCHER.—Daily yield, 400 tons of ore, keeping the mills steadily running. Sinking the winzes from the 1400 to the 1500-ft level, has shown no particular change.

IOWA.—The new hoisting machinery has arrived at the depot of the Virginia and Truckee railroad, and will be transported to the mine and put in active operation at the earliest possible moment.

YELLOW JACKET.—A flow of water, encountered in the east cross-cut of the 1840-ft level, has stopped all works in that portion of the mine for the present.

UTAH.—All of the new pumping machinery is on the ground, and its erection is being accomplished as fast as the nature of the work will permit.

JACOB LITTLE CONSOLIDATED.—The developments of this mine are now in a very encouraging stage of successful advancement, the drifts showing considerable quantities of good milling ore.

JUSTICE.—Sinking the main incline below the 800-ft level progresses well, but somewhat slower, owing to the hard character of the rock encountered and the increase of water. The main drift south, opening the 800-ft level, is now in 44 ft from the incline, with the face in porphyry. Considerable water is met with thus far, which, however, may decrease as the drift passes into the main ledge.

EUROPA.—Since last week's report the face of the east drift or cross-cut, from the winze, 115 ft below the main adit level, has run through a very fine stringer of metal-bearing quartz, six inches wide, giving fair assays. It is a strong feeder of the main ledge, but the angle of its inclination shows the ledge is probably a little further distant than has heretofore been supposed.

SAVAGE.—The erection of the new and powerful incline machinery, is making steady headway. Prospecting on the 2000-ft level shows no change of interest for the week.

LEO.—Very favorable progress is being made in driving the main tunnel ahead, the ledge containing well defined and large, and carrying a promising character of vein matter.

IMPERIAL EMPIRE.—The clay seams and quartz in the face of the main east cross-cut on the 2000-ft level, have considerably increased during the week. The rock in the bottom of the main incline is much harder, and blasts badly.

AMERICAN FLAT.—The ore prospects on both the 750 and 850-ft levels are growing more encouraging as the work progresses. The ledge formation on the 750-ft level, is showing much more compact and better defined than on the levels above.

OVERMAN.—The flow of water at the bottom of the shaft shows no diminution since our last report.

ORIGINAL GOLD HILL.—Since our last report, the cross-cut from the main south drift to run beneath or intersect the valuable ore development found in the upraise above that level, has progressed well and will be in where it ought to be in a few days.

JULIA.—Sinking the main shaft is making

good progress. It is now down 1240 ft. The rock in the bottom is working much softer.

CAWDM POINT.—The prospecting and cross-cutting on the 1600-ft level goes on as usual with no important changes to chronicle. Opening the 1700-ft station is making rapid progress. The old ore breasts and stopes show but little change. Daily yield 400 tons of ore.

MEXICAN.—The north drift on the 1465-ft level of the Ophir is showing considerable of an improvement, the quartz is rapidly improving in looks and the assays gradually on the increase.

SILVER HILL.—Nearly all the new pumping machinery is on the ground ready to place in position for the future operations. Its erection is being pressed with all the vigor possible.

BULLION.—The ledge continues to show a steady improvement on the 800-ft level. Driving the main north drift on the 1700-ft level of the Imperial is making rapid progress still.

WOONVILLE.—The ore stopes on the 300-ft level continues to show finely. The winze below the 300-ft level is down 30 ft still in ore.

KNICKENOCKER.—The new pumping machinery is working splendidly. Cross-cutting the east clay wall on both the 600 and 700-ft levels has been commenced, and some excellent results may now soon be looked for.

FLORIDA.—The heavy new hoisting and pumping machinery has about all arrived, and as soon as practicable will be put in working position.

BEST AND BELCHER.—Driving the south drift from the bottom of the 1700-ft winze is making steady progress, the face still in vein material.

Idaho.

GOLDEN CHARIOT AND MINNESOTA.—*Oreghes Avalanche*, March 10.—These two favorite mines are owned and worked by the Golden Chariot mining company, under the efficient and able management of Col. Jas. H. Keown, superintendent. Work in both mines is being pushed ahead with all possible dispatch. The 10th 11th and 12th levels of the Golden Chariot will soon be opened up ready for taking out ore. The Minnesota shaft will in a short time be down a sufficient depth to admit of the running of drifts to connect with the lower levels of the Chariot. When these connections are made, it will afford the largest body of ore ready for stoping ever before opened in these mines. We expect soon to hear the company's mill pounding away on rich ore, which will give such results in bullion as to equal, if not surpass, any shipments heretofore made from these two mines.

WAB EAGLE.—Stoping and raising ore has been commenced in good earnest at this mine, and preparations are being made to commence hauling ore to the mill. Twenty-five tons is now the average daily yield of ore from this mine. Additional hoisting facilities will soon be added, the machinery for which is now on the way from San Francisco, and when put in place, Wab Eagle will produce double the quantity of good milling ore that it now does per day. Early and good shipments will be made from this mine the coming spring, and we predict regular dividends to stockholders next summer.

RED JACKET.—Work in the prospecting drifts and winzes of the Red Jacket is being pushed ahead vigorously by Superintendent C. S. Miller, and we understand that the prospects are very flattering for striking ore soon. This mine has produced as rich ore as any in camp, and the finding of ore at the depth now reached would be a guarantee of an extensive and permanent mine.

Utah.

LITTLE COTTONWOOD.—*Steven's Utah Record*, March 5: The principal mines in this district have been vigorously worked, and the outlook for next summer is very promising. The weather was fine during the whole of the month and shipments of ore continued daily. A new and extensive development is reported in the Flagstaff. Work on the Victoria and Imperial tunnel is being pushed forward and fine ore reached. The damage done in building and tramway of the Vallejo, by the snow slide in January, has been all repaired, and the extraction of ore and shipments resumed.

BIO COTTONWOOD DISTRICT.—Everything is going forward without interruption. The principal mines are being worked and continue to ship ore and improve in appearance. The Dolly Varden mine has struck it again in the lowest workings and indications are most favorable. The Richmond and Teresa are involved in a law suit in regard to title of property, and this has induced the owners of the Richmond to suspend the shipments of ore, though the portion that is richest in mineral is not involved. The Evergreen is said to be looking well, and very favorable for a good yield of ore the coming season. The snows have been severe, still, the fall of snow during the winter is at least thirty per cent. less than last season.

BINGHAM CANYON DISTRICT.—There has been no diminution in work on the Spanish mine, the yield continuing as large and the quality of ore the same. The deepest level is 430 feet. The ore is being purchased by the Flagstaff Smelting Co. The Winnamok main tunnel is down 700 feet; from ten to twelve tons of ore are being taken out of the mine daily.

The Neptune and Kempton are reported to be in a very flourishing condition and yielding largely. The mines have been connected at the third level, exposing a fine body of ore. The district, from all accounts, seems to be steadily improving and the mines generally yielding satisfactorily.

New Combination Shafts.

Mining shafts far east of the present workings on the Comstock ledge seem to be the order of the day. The ledge pitches in that direction, and the advantage of sinking directly over an ore body is apparent. The original mining works were directly upon the outcroppings above B street. Ten years ago the Gould & Curry, Savage, Chollar, Hale & Norcross, Mexican, Ophir and several other companies, had splendid hoisting works and elegant offices on the side of Mount Davidson. The same was true with the Imperial, Empire, Confidence and other mines on the west side of Gold Hill. As time advanced tunnels were run in lower down on the hillside. The famous Gould & Curry tunnel required over two years in its construction, as it passed the greater part of the way through hard rock. At that time a great portion of the business of the city was done on B street, as the large brick fire-proof buildings between Union street and Sutton avenue still bear witness.

Change of Base.

After a few years it was found necessary to move the hoisting works further east. The original shafts were abandoned, new ones were sunk and buildings erected on their present location. The companies, which were combined into the Consolidated Virginia, profited by the example of their neighbors and opened their shaft between E and F streets. The advantage of a change of base all along the line has been obvious, both in new discoveries and in easier and less expensive workings. The ledge has now, however, been developed to so great a depth that a still further advance toward the east has become necessary. The Imperial and Empire companies combined and jumped across the road in Gold Hill and sunk a joint shaft. The California and Consolidated Virginia entered into a similar arrangement and are rapidly driving ahead the O. and C. shaft several hundred feet east of the present works of the latter.

A New Enterprise.

The Chollar, Hale & Norcross and Savage companies contemplate sinking a joint shaft in the vicinity of the County Hospital, and are making preparations to begin active operations. The shaft when completed will be over 3,000 feet in depth. In order to transport the timbers and machinery a branch railroad is necessary which must cross a deep ravine in its course. A large force of men are at present engaged in filling in this ravine and in grading for the track. The new road commences near the short railroad tunnel south of the round-house, and after crossing the ravine, the track will wind around the side of the hill, east of the Mint mine, until it reaches the site of the new shaft. The grade is not steep at any point, but the construction of the road bed will involve considerable expense. We learn that other leading companies intend sinking shafts farther east. When these new works are completed, the lower portion of the Comstock will be thoroughly explored in search of

New Bonanzas.

Which may be struck at any time. It is this expectation that leads companies, at present out of ore, to levy assessments and continue prospecting, as experience has shown that a good body of ore will soon repay all previous outlays and send the stock up to a high figure. From the bonanza of the Belcher and Crown Point, \$50,000,000 were extracted in three years, and \$25,500,000 paid in dividends. The ore at present in sight along the line of the Comstock assures the prosperity of Virginia for many years to come, and in the meantime it is almost certain that other discoveries equally as valuable will be made.—*Virginia Chronicle*.

Hardness of wood.

It is a great convenience to know the comparative value of different kinds of wood for fuel. Taking shell bark hickory as the highest standard of our forest trees, and calling that one hundred; other trees will compare with it for real value as follows:

Shellbark Hickory.....	100	Yellow Oak.....	60
Pignut Hickory.....	85	Hard Maple.....	58
White Oak.....	84	White Elm.....	58
White Ash.....	77	Red Cedar.....	55
Dogwood.....	75	Wild Cherry.....	55
Scrub Oak.....	73	Yellow Pine.....	54
White Hazel.....	72	Chestnut.....	53
Apple Tree.....	70	White Poplar.....	51
Red Oak.....	69	Butternut.....	49
White Birch.....	65	White Birch.....	49
Black Walnut.....	65	White Pine.....	30
Black Birch.....	62		

But it is worth bearing in mind that there is a very considerable difference in the woods of the same species, according to the manner and the soil on which they grow. A maple that grows slowly on an upland pasture, standing alone or apart from other trees, will last much longer and give out a greater degree of heat than one that grows in a swamp, or in the midst of a dense forest. A tree that grows in a forest or on a wet, low, rich ground, will be less solid and less durable for fuel, and consequently less valuable than a tree of the same kind that grows on a dry and poorer soil. For sale, to be sure, one would be just as good as the other. To the purchaser, oak is oak, and pine is pine, but for home, the tree grown on dry upland and standing apart from others is worth a great deal more. All these rules hold good as regards timber.

The people in and around French Corral, Nevada county, complain of the great scarcity of water for mining purposes.

Trinity County Quicksilver Mines.

From an article in the *Trinity Journal* on the mines in Cinnabar district we extract the following:

Worland & Butler's shaft was visited and shows very rich indeed in cinnabar, being literally striped with vermilion stringers. Mr. Butler showed us a small hole—probably six cubic feet in extent—in the side of the shaft, from which three tanks of quicksilver had been taken. At the present time they are not getting out any ore, but are running a tunnel to strike the body uncovered in the shaft. They have made arrangements for the transportation of a four ton furnace from San Francisco and by the time it can be got there and placed in position they will have plenty of ore to run it with. Mr. Butler informed us that one lead on the mine had been prospected for seventy feet in width and found to be good furnace ore for all that distance. From what we saw, we are satisfied that the mine of Worland & Butler is one of the richest in the district.

Hawsett & Lytle have commenced at the back end of their tunnel and are stopping to the front, everything back of them being covered so that nothing could be seen. The ore pile at their dump is sufficient, however, to show the richness and extent of their mine—being a small fortune in itself. They have three large retorts at Hawsett's camp which will soon be in position ready for operation. The firm have just contracted with James Mullins for the transportation of ore, from the mine to the retorts. Both of the companies just mentioned will turn out large quantities of quicksilver during the summer.

The Trinity Q. M. Co. continue work on their tunnel, being in a distance of 215 feet without any exciting developments as yet, although they are not far enough into the hill to strike any extensive deposit. From rock indications it is thought they will soon reach the vein on which Hawsett & Lytle are at work. Rumlert & Loring, B. C. Wattles, Jes. E. Carr and others have men at work prospecting their little work, but owing to bad weather of late but little work has been done and no developments made beyond the striking of an occasional stringer. H. C. Wilt has found excellent surface prospects on this mine, north of Worland & Butler—getting a pound and over of pure cinnabar to the pan. It is estimated that he can rock out 100 pounds per day. Hank is erecting a cabin on his ground and expects to strike it big when he gets to work in earnest. S. J. Dickinson is building a cabin on the claims of the Bonanza company and after getting comfortably domiciled will begin prospecting. The new Bonanza is favorably located, and, being interested, we hope it will at least equal its Nevada namesake. Several old locations have been relocated and many others will be served likewise unless work is soon commenced on them. No ground will be allowed to lie idle in that district this summer. About forty men are there now and the number is continually increasing. A hotel and stable are badly needed there, and the men who get a fair start in that business will have as good a thing as the best of the mines.

Fearing more storm, our party, with the exception of the Judge, left Cinnabar Thursday afternoon at 2 o'clock and arrived at the Center before 7 that evening. Next day we made home well pleased with our trip and treatment and resolved to visit Cinnabar again when good weather comes and make a full report on the mines there. Rich developments may be expected now that much prospecting will be done, but enough is already in sight in the Hawsett & Lytle and Worland & Butler mines to insure a large settlement and lively times at Cinnabar. For a distance of eight miles cinnabar has been found, so that the field for prospecting is large and as favorable as it is extensive.

WINE AMONG THE ANCIENTS.—The Greeks and Romans had their favorite wines; the Roman Ferien was one of the most celebrated. This was grown near Naples, a locality which is still celebrated for its wines. The Romans were accustomed to apeak of the wine of a particular year, as, for instance, of that of the Optimum year, or the year of Rome 632, when Optimus was consul, much in the same way as we now speak of the wine of 1866, or any other year in which it has been of exceptional good quality. Those of the Romans were all still wines, and as they do not seem to have understood the art of bottling, it was preserved by pouring a little oil into the neck of the flask. Pliny states that there were fifty-four Italian and ninety-six foreign wines held in esteem in his time. Horace states that the Greek wines were imitated, so we see that imixing is no new trade. The Romans, not understanding the use of sugar, in order to make their wines thick, boiled down the must. They used skins for the purpose of holding it, as well as amphorae made of clay. The saying in the Bible, that new wine is put in new bottles, most likely has reference to the use of these skins, which would become weak in the course of time. The Arabs still use these skins for the same purpose, and the poorer classes in Spain also make use of them. One of the most laughable scenes in Don Quixote, is the account of his attack on the wine skins. Of the manner in which the ancients made their wines we can only conjecture, but the press in some form was early known.—*Jour. of App. Chemistry*.

It is rumored that the Central Pacific folks contemplate moving their machine shops at Truckee to Reno, and those at Wadsworth to Humboldt.

Progress in Tin Manufacture.

Working in tin ware, simple as it appears at first sight to be, has become in these days of modern improvements, quite an intricate art, involving, whenever conducted on a large scale, much complicated and expensive machinery. At the commencement of the present century, the manufacture of tin goods, even in England, was carried on by small makers, scattered all through the kingdom. The trade was also conducted in a manner quite as primitive on this side of the Atlantic. A few large manufacturing had been established in both this country and in Europe, but even then but little machinery was used, and the men employed in Great Britain were but little better than wandering gypsies. A more intelligent and permanent set of workmen were engaged in the business in this country.

At that time and for many years afterwards, so little progress had been made in the art, that even so small an article as a patty pan was cut out in several pieces and soldered together—the art of pressing out even such a small article, from a single piece of metal had never been conceived of. Such a thing, in fact, was not successfully accomplished until the year 1830—and was then considered quite an event.

The success which attended the experiment on so small a scale, soon, however, led to those vast subsequent improvements which now enable the tinware manufacturer to turn out, by that process the largest dishes, covers and basins. Even a good sized tub may now be "pressed" out of a single piece of metal.

Although hollow ware, such as tea-pots, etc., have long been made from tin plate; such goods commended but a limited market from the fact of their necessary disfigurement by the inevitable seams and joinings. Lack of facilities for turning out such articles from block tin, especially of being still farther beautified by the electro-plating art, at a small cost, was also a great drawback to their general introduction. Of late years, however, machinery has been devised whereby articles of this description are made by the combined action of stamping and "spinning," by which a firm, smooth and brightly polished surface is produced, equal to those made of block tin and electro-plated.

Stamped from one piece of iron, tinned, wheeled, planished and polished by improved methods, the bright silvery color, beautiful outlines and artistic finish of wares made by this process, render them formidable rivals to the more expensive and less durable electro-plated Britannia goods. Their not requiring to be cleaned more than once where plated articles require five or six polishings, is also a matter greatly in their favor.

Wrought hollow ware now forms a large and constantly increasing department of tin plate manufacture. These articles now include sauce-pans, stew-pens, frying-pans, and even tea and coffee cups, and have largely increased this field of manufacture, and being made of wrought, rather than cast iron, are at once lighter and less liable to fracture. The above gives some faint outline of the great strides of improvement which have been made in what was but recently considered a very simple business, and of comparatively limited application.

Cabinet Making a Fine Art.

The cabinet maker is one who manufactures fine articles of wood furniture. Such a worker is really an artist, and his field of usefulness is wide and varied. The cabinet maker is distinguished from the joiner, mainly from the fact that he is supposed to apply himself to his work more artistically. Both join wood together, which is the primary occupation of the joiner—who joins more in the rough, as in house-building or in the manufacture of the coarser descriptions of furniture.

A cabinet maker, and indeed every other modern artisan ought to be able to design as well as construct. It is not sufficient at this day that a person should be able to simply copy the works of others—they should be able to design original articles in their line. Public taste in matters of furniture has come to be very exacting and quite aesthetic in its character. The beautiful in art is now sought for largely in household adornment, and new and beautiful designs are difficult of attainment.

A successful cabinet-maker must be able to design, and should seek to cut loose as far as possible from the habit of imitating others. Originality is essential to success. If one wishes to carve a medalion let him take a living or else an ideal subject—don't copy. If a leaf, or vine, or fruit is desired, place the leaf or vine or fruit before you for a copy, and not the work of some one else who has already produced the same. If one desires that his work should be admired and live after him he must put his soul into it—breathe into it as it were, a living spirit, as did the sculptors, and painters, and architects of old, whose works have come down to us through the centuries.

Born at the Ophir and California they are prospecting in advance on their lower levels with diamond drills. The California is said not to be working very satisfactorily; but the Ophir drill is now working very well.

DARWIN, the new settlement in Coso district, Inyo county, contains about sixty houses, and in the opinion of some will before long be the largest town in the county. The mines are very promising.

Amateur Engine Building.

It is one of the first desires of most young men when they go to learn a machinist trade, to build for themselves a small working model of a steam engine. As soon as the young mechanic has learned the use of tools he is very apt to apply much of his leisure time to constructing the parts of a steam engine and fitting them together. Being unprovided with castings he has to commence with his patterns and make the castings himself, something quite foreign to the trade which he is learning. Either this has to be done or the various parts have to be worked out by the file. Either process is very tedious; but the interest felt in finishing the job holds on to the last—until the machinery is completed, and the young mechanic has the pleasure of turning on the steam and seeing, for the first time, a steam engine of his own make working away under a full head of steam! The pleasure of that moment more than makes amends for all the trouble, toil and patience which has been bestowed upon his pet.

We have often wondered why some one has not got up one or two different sized sets of patterns for small engines, of a something more than toy size, for sale to such as might be desirous to exercise their mechanical ingenuity in the way of finishing up and putting together the pieces which is all of engine building that properly belongs to the machinist. There are no doubt many young men, who are not engaged in learning trades, and who do not even contemplate doing so, who would be pleased to provide themselves with tools necessary for such work, and spend their leisure hours as amateur mechanics, if such results could be so readily realized. The cost of such a set of castings would be small, in the rough, and would be within the reach of almost every one, and their possession and finishing up would no doubt be the means of developing many a mechanical genius which might otherwise lie dormant forever.

Such a set of castings should be represented by a cylinder, say 2 inches in diameter, with a stroke of 4 inches, and a 10 or 12 inch balance wheel. Other sets, a size smaller and a size larger, might also be provided, for such as might prefer a smaller or larger engine.

Such a set would comprise 14 pieces, as follows:—Bed-plate, balance wheel, crank, pillow block, eccentric, eccentric bands, slides, cross beads, cylinder heads, piston, steam chest, stuffing boxes and slide valve, and the inevitable whistle might be added, if desired. These might be furnished simply as iron and brass castings in the rough, to be finished up, polished and put together by the amateur. Here is a chance for somebody—some of our brass foundries for instance—to make a small, and, we think, a profitable addition to their stock of castings. Who will furnish them?

Underground.

At the Geological Society of Glasgow annual meeting the President (Sir William Thomson) delivered an interesting address, which was greatly appreciated by the members. The subject dealt with was "Underground Temperature." Sir William explained at the outset that the mathematical theory of underground temperature involved phenomena which might be divided into two classes—periodic and non-periodic. The periodic phenomena occurred over and over again with perfect regularity in successively equal intervals of time; the non-periodic might be approximately periodic, or irregularly periodic, without fulfilling accurately that strict definition. But, on the other hand, the action which had no periodic character whatever might be irregular, or there might be a gradual secular variation. There might be three classes of phenomena—secular variation, irregular variation and periodical variation. He then described the mathematical theory of Fourier, as applied to the periodic, observing, in passing, that it was equally convenient for dealing with all three classes. That theory was one of the most beautiful pieces of application to the mathematical instrument they had in the whole history of science. It had constituted a new branch of mathematics, and Fourier, Sir William mentioned, invented it for the purpose of analysing the phenomena of the conduction of heat through solids. He spoke of the investigations of Peclet, Armstrong, Quetlet, Tait and Forbes into the conductivity of bodies, and he exhibited a diagram showing the results obtained by Forbes from thermometers placed at depths of 3, 6, 12 and 24 feet below the surface in Creigleith quarry, the Experimental Gardens, and the Clifton Hill, Edinburgh. The result of these observations, which Forbes commenced and Sir William continued, showed that the variations were greater near the surface, that a higher temperature was generally indicated at a later period at the greatest depth, and seemed to show that the sandstone of the Creigleith quarries had a greater conductivity than the trap-rock. Sir William concluded by referring to the temperature of the earth as indicating its former condition, and be promised at some future time to give the society another address on a kindred subject.

EUREKA mining district continues to turn out large quantities of ore. Last week the Richmond produced 140,000 pounds, and shipped 60,084 pounds, and the Eureka Consolidated produced 168,260 pounds, and shipped 185,435 pounds, making the total production 308,260 pounds and the shipment 245,519.

USEFUL INFORMATION.

How to Treat a Watch.

A Scientific watchmaker, Mr. Nelthrop, thus advises, with reference to our vest-pocket companion: "A watch is much like a child, requiring uniform treatment, that is to say plainly, not over indulged to-day, neglected to-morrow. Wind-up should be performed regularly, with a steady and uniform motion, not moving both hands, and nearly as possible at the same hour daily. A watch should always be kept at the same temperature, as nearly as possible. Left over-night on a stone mantel-piece, it is sure to gain, or if the oil gets thickened, it may stop, in no started again by the warmth of the pocket. The regulator is too often viewed as an appendage more to be looked at with wonder than to be used, while the persons who can explain the theory of its action are few in the extreme. Yet the task of learning enough about a watch to become capable of talking intelligently about it, and exercising the control over a 'jobber' which that knowledge is certain to give, is but slight, and it ought to be reckoned as blameworthy to be ignorant about one's watch as to know nothing of the merits of one's boots or clothing." Mr. Nelthrop gives to the uninitiated a few hints as to the purchase of a watch, which are worth reproducing. The case, be it gold or silver, should be correctly made and of fair thickness; the hinges close and smooth; the glass well fitted; the dial of clear, bright enamel, the seconds snail, the whole of good weight when held in the hand. When the dome is opened—for it is better that a watch-case should be so made, though more expensive—the brass work should look well finished, the edges smoothed off, the jewels pale in color, but of a fine, clear lustre; the action of the spiral spring should be even, when the watch is set going.

SECURING SAFETY IN THE USE OF STEAM BOILERS.—The case of a boiler has much to do with its safety and working age, and the cases of neglected boilers show how important, reliable and intelligent engineering talent is. There are many who are ever ready to put forth all sorts of theories and causes of steam boiler accidents. But as a general thing they are not persons who are familiar with boilers in daily use, or if they own boilers, their experience is confined to their own practice. It will be readily admitted by every thinking person that as an experience gained from examining boilers in different parts of the country, of all types and under all the varying conditions of use to which boilers are subjected, will be more valuable than any experiments with one, two or three boilers, or with the practical use of the number in any one of the large manufactories in the country. The views obtained from a large collection of facts resulting from actual experience, and from a close and careful examination of facts connected with steam boiler explosions, continued through a series of years, will be likely to lead to much more important and valuable conclusions than could any reasonable number of experiments made in testing boilers and straining them, under special conditions, to the bursting point, as is done (and that to advantage) with cannon. Such observations are now being made by reliable parties; and reports may be expected, before long, which will no doubt add much to our real knowledge in this important direction.

AN APPROPRIATE EMBLEM.—Bedstead designs might more frequently make use of the lotus in these carvings. It is one of the most appropriate designs which can be taken from the vegetable kingdom. Pliny says of these plants:—"It is reported when the sun goes down, their heads, which are like those of the poppy, close up with the leaves and sink under water, where they remain shut up until the morning, when they appear above the surface and open."

RUBBER JOINTS.—A Scientific American writer says: "In making a rubber joint, take a piece of chalk and rub it on the side of the rubber and flange where the joint is to open, and, when required, they will come apart easily and not break the rubber; although the latter may be burnt and hard. Repeat the chalking before screwing up, and you will have as good a joint as ever, and the rubber can be used a number of times."

GLUE TO RESIST FIRE.—The London *Furniture Gazette* gives this recipe: Mix a handful of quick lime in 4 ozs. of linseed oil; boil to a good thickness, then spread on plates in the shade and it will become exceedingly hard, but may be easily dissolved over the fire, and used as ordinary glue. It resists fire after being used for gluing substances together.

VARNISH FOR METALLIC SURFACES.—A foreign authority says that alcoholic varnish can be made to adhere more firmly to polished metallic surfaces by adding one part of pure crystallized boric acid to two hundred parts of varnish. "Thus prepared, it adheres so firmly to the metal that it can not be scratched off with the finger-nail; it appears, in fact, like a glaze."

To true a corundum wheel, adjust it in the lathe and revolve it very fast, holding a piece of corundum stone against the surface. It is said the piece will melt and unite with the wheel, making the periphery perfectly true,

To prevent rusting.—Boiled linseed oil will keep polished tools from rusting if it is allowed to dry on them. Common sperm oil will prevent from rusting for a short period. A coat of copal is frequently applied to polished tools exposed to the weather. Woolen materials are the best for wrappers for metals. Iron and steel goods of all descriptions are kept free from rust by the following: Dissolve 1/2 oz. of camphor in 1 lb. of hog's lard, take off the scum and mix as much black lead as will give the mixture an iron color. Iron and steel, and machinery of all kinds, rubbed over with this mixture and left with it on for twenty-four hours, and then rubbed with a linen cloth, will keep clean for months. If machinery is for exportation it should be kept thickly coated with this during the voyage.

STEAM-BOILER INSPECTION.—It is notorious how incautious we all are when our life and property are jeopardized. To-morrow, we will attend to that leaky boiler; next week, we will let down our fires for repairs; and thus it goes, until some fine morning we are called to view the utter demolition of our once beautiful and powerful factory, together with the forms of hundreds of innocents perishing in the seething flames and ruins. Let our manufacturers, engineers and superintendents ponder well this question of steam-boiler inspection and insurance, and no longer hesitate as to what course to pursue.—*Coal and Iron Record.*

When steel instruments have been injured by over-heating, they may be restored to their normal condition by heating to a cherry red and covering with the following mixture, or salve: Two parts of horn-slings, 10 parts talow, 1 part sal ammoniac, 1 part pulverized charcoal, 1 part soda. When the steel gets cold, it may be hardened in the usual manner.

A well tempered bar spring will lose much of its elastic strength by filing off a very thin scale from the surface.

GOOD HEALTH.

Take Good Care of your Servants.

[Written for the Press.]

The servants of our bodies (our most valuable servants) are the teeth, the stomach, the liver, etc. They are all very easily and very often abused. In fact we abuse them without being aware of it. The stomach is the subject of the most abuse of all the bodily organs. We don't expect the servants of the farm or the kitchen to work any longer than the number of hours they agreed to work; but we abuse the poor stomach by forcing it to work at all hours in the day and even in the night, when all other organs of the body are at rest. One way of abusing the stomach is to not nasticate the food thoroughly, and then the stomach has to do the work that the teeth and mouth should have done. When food is thoroughly chewed it is well moistened with saliva. But when it is bolted with little or no chewing, then the stomach has to furnish more than its share of gastric juice to wash up what should have been done in the month. The stomach has more muscular exercise to perform in the process of digestion than most people are aware of. It secretes gastric juice from the arterial blood, which is held in a thousand little glands in the mucous membra in, and when food is eaten these glands emit this gastric juice into the chamber of the stomach to moisten the food and at the same time the muscular coats of the stomach contract and dilate, and take the food through a kneading (or churning as some physiologists call it) process, to mix it thoroughly with the gastric juice.

This secreting gastric juice and working process is kept up until every particle of food is thoroughly digested. The time required for digestion in a healthy person is from one to three hours according to the character of the food eaten. When a person eats three times a day, the stomach has the proper amount of rest. But unfortunately very few people do eat but three times a day. Some eat every time they happen to see food. And the stomach will attend to its business as long as it has the vital power to do so, even if it is imposed upon. Thus, however, after a person eats between meals the stomach will commence to digest and do its work as well as its vital power will admit of.

Some call it second nature, when they have acquired an unphysiological habit. A person may live awhile on second nature; but first nature will come at some time and demand settlement, and then second nature will be found bankrupt. Then what happens? Why, if the stomach is burdened with overwork, it is going to fail to do its work well, and then some one of the myriad forms of dyspepsia is sure to follow. Then follows a succession of secondary diseases; and the sufferer will blame the country, the climate, everybody and everything, except his own irregular habits. Sour stomach is one of the most annoying and most disastrous forms of dyspepsia. It is one great cause of so much premature decay of teeth.

Children should be taught regularly in eating from their infancy. It is mistaken kindness to feed children every hour in the day, if they happen to ask for food so often; but most people do it, and the consequence is, that

one half the people are dyspeptics before they arrive at man and womanhood. The other side of the picture—I have had the pleasure of seeing a few families who practice regularity in eating, with other physiological reforms (that only a few are interested in), and the good health they enjoy is worth a hundred times the pains required to take care of the health. Health journals are much cheaper than aches and pains and doctors' bills. N. A. PROCKENS, M. D.

Tincture of Arnica Poisonous to the Skin.

One of the most popular articles in the household materia medica is tincture of arnica. It is used in almost every family as an external application for sprains, bruises, and pains generally. But, according to Dr. J. C. White, it often exerts a poisonous action on the skin. In the *Boston Medical and Surgical Journal* for January 21, 1875, he describes in detail three cases in which it produced acute inflammation or eczema. Arnica, he says, "must therefore be regarded as an irritant poison when applied to the skin of some persons." Even when it is not harmful he believes it to be useless for the purposes for which it is employed. Its properties reside in an acrid resin and a volatile oil. For its reputation as an application for sprains and bruises, "it may thank the alcohol associated with it, for this, beyond doubt, is the only active agent in such application."

When arnica is used so extensively, why are not cases of poisoning by it more common? To this question Dr. White replies:

"I believe that they do occur not infrequently, but that they are not recognized. The appearances which follow its use are no doubt often mistaken for the immediate effect, or the sequelae of the injury or other trouble for which it was applied. Even the physician, there can be little doubt, often fails to recognize the artificial nature of the eczema he is called upon to treat, and to connect it with the prior application of arnica to the skin. The almost universal belief in its harmlessness, too, would prevent in most cases the patient from communicating to the physician the fact of its use before the appearance of the disease."

It is not to be wondered at, however, that physicians are so little acquainted with these poisonous properties, when we see how little mention is made of them in medical literature. The works on materia medica that I have at hand give it a more or less feeble commendation, but make no allusion to its injurious action upon the skin. Very few of the works upon toxicology place arnica among the poisons, and Van Hasselt, who gives the fullest account of its injurious results when administered internally, says nothing of its action upon the skin. Neither do I recall any reports in medical journals of cases of such affection. In a long list of substances enumerated as capable of producing eczema, in his chapter on this disease, Hebra includes arnica without special mention; but in another article he says: "Some medical men suppose that tincture of arnica is a perfectly harmless remedy. But I would give a friendly warning to those who advocate its use; unless, indeed, they propose to employ it homoeopathically and in infinitesimal doses. In the proportion of a drop of the tincture to a pail of water, this substance may certainly be applied without any risk of doing harm."

"I have in practice had abundant occasion to observe that the tincture of arnica, even when much diluted, acts most injuriously upon the skin of some persons. Fox, in his brief remarks on medicinal rasches says: 'Arnica may produce erythema, and swelling of the part to which it is applied, or it may excite a real eczema.'

These facts ought certainly to be known by physicians, and by everybody who has been in the habit of using this popular tincture. The extent to which it is used may be inferred from the fact that there are single houses in Boston that sell several thousand pounds of arnica flowers every year. The herb is employed in veterinary practice, but full one-half of all that is sold goes to supply the demand for the tincture as a household "pain-killer." The alcohol without the poison would be cheaper as well as safer.—*Boston Journal of Chemistry.*

Sleeplessness.

To take a hearty meal just before retiring is, of course, injurious; because it is very likely to disturb one's rest and produce nightmare. However, a little food at this time if one is hungry, is decidedly beneficial. It prevents the gnawing of an empty stomach, with its attendant restlessness and unpleasant dreams, to say nothing of probable headache, or of nervous and other derangements, the next morning. One should no more lie down at night hungry than he should lie down after a very full dinner, the consequence of either being disturbing and harmful. A cracker or two, a bit of bread and butter, or cake, a little fruit—something to relieve the sense of vacuity, and so restore the tone of the system—is all that is necessary.

We have known persons—habitual sufferers from restlessness at night—to experience material benefit, even though they were not hungry, by a very light luncheon before bedtime. In place of tossing about two or three hours as formerly, they would soon grow drowsy, fall asleep and not wake more than once or twice until sunrise. This mode of treating insomnia has recently been recommended by several distinguished physicians, and the prescription generally attended with happy results.—*Scribner's Magazine.*

DOMESTIC ECONOMY.

Salads and Dressings.

"Daisy Eyebright" always writes well and always tells her readers things true and useful, whether her subject be flower gardening, cookery, or domestic economy. She says, for instance, of salads (in the *Country Gentleman*) that if we would use them, as the French do, as an article of daily food, we should not engender so many disorders of the blood as we do by eating so much fat meats, and butter and sugar in its varied forms of cakes, pies, puddings, etc. She offers the following recipes, which we hope our fair housekeepers will try for themselves:

MAYONNAISE DRESSING.—This is for lobster or chicken salad, and is made as follows:

Break the yolks of three raw eggs into a salad bowl, add a little salt and white pepper; stir it with a wooden spoon with the right hand, while with the left you add, very slowly, about half a pint of pure salad oil, poured from the bottle held in the left hand. Beat it for twenty minutes, and add pepper and salt to your taste. Beat the whites of two eggs to a stiff froth, and stir rapidly into the dressing. Now add about two large spoonfuls of vinegar, more or less, according to its strength, and blend all thoroughly together until it is as smooth as glass; if not so, add a few drops of cold water to mingle the whole mixture. Take the lobster from the shell; leave the legs and the "coral" to be used as garnish; cut the remainder into small dice and place in a deep bowl; add to it small heads of coos lettuce (which is the light green variety, and very tender, but the common kinds will do), garnish the dish with capers and lobster claws and "coral," sliced hard-boiled eggs and olives, first, turning the mayonnaise all over the lettuce.

If you desire to make chicken mayonnaise, roast the fowls, basting them frequently with butter dissolved in water; when roasted tender, remove the flesh from the body, wings and legs; cut in small mouthfuls, and add either celery, lettuce, or chopped cabbage—the first, if well blanched is preferable. Garnish with slices of boiled beets, hard-boiled eggs, and olives.

CABBAGE AND HAM SALAD.—Take two small heads of cabbage, well washed, and chop them quite fine; slice off a dozen or more thin slices of tender boiled ham. Mix the two together in a salad bowl. Make a dressing of two raw eggs, mixing the yolks with half a teaspoonful of mustard, stirred up in boiling water; then add three tablespoonfuls of sour cream, just skimmed from the pan, or one small teacupful of salad oil, poured in very slowly, as directed for mayonnaise. Stir for ten minutes, adding a little salt and pepper. Beat the whites of the eggs to a froth, and add to it; also four tablespoonfuls of vinegar. This makes a delicious side dish, or a course at the dinner-table, and the housewife will find it a toothsome substitute for a hot dinner when the mercury mounts high up among the naeties, and there is ironing or washing to attend to. Chopped cold boiled potatoes can also be added; and the dish can be prepared out of cold boiled corned beef chopped fine, or from cold roast veal, beef, or mutton. Lettuce can be substituted for cabbage if preferred, and the mustard can be left out.

BOILED CABBAGE SALAD.—Boil a Savoy cabbage until tender; then drain and chop it. Serve with a salad dressing, made out of two hard boiled eggs mashed very fine, three tablespoonfuls of thick, sour cream, one teaspoonful of mixed mustard, one teaspoonful of salt, two tablespoonfuls of strong vinegar. Stir until perfectly smooth, and turn over the cabbage.

TO TAKE OUT BRUISES IN FURNITURE.—Wet the place well with warm water, then take some brown paper five or six times doubled and well soaked in water, lay it on the place, apply on that a hot flat-iron till the moisture is evaporated, and if the bruise is not gone, repeat the process. You will find after two or three applications that the dent or bruise is raised level with the surface. If the bruise is small, soak it well with warm water, and hold a red-hot poker very near the surface, which is to be kept continually wetted, and you will soon find the indentation vanished.

HOME REPAIRS OF PLASTERED WALLS.—Small holes in white plastered walls can be easily repaired without sending for the mason. Equal parts of plaster of Paris and white sand—such as is used in most families for scouring purposes—mixed with water to a paste, applied immediately, and smoothed with a knife or flat piece of wood, will make the broken place as good as new. The mixture hardens very quickly, so it is best to prepare but a small quantity at a time.

APPLE SNOW.—Pare the apples, halve and core them; put them to boil with a little water and one cupful white sugar. When the apples are cooked, lift them out without breaking; boil down the sirup and pour over. On the top place a few spoonfuls of whites of eggs; beaten to a stiff froth and seasoned with lemon.

WHITE CAKE.—Two eggs, two cups of white sugar, one cup sweet milk, one-half cup butter, beat to a cream; two tablespoonfuls cream tartar, one teaspoonful soda, three and one-half cups flour. When baked, sprinkle the top with white sugar, and place spoonfuls of jelly on the top.

MINING SCIENTIFIC PRESS.

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.—The District Telegraph; Students in the Field; Hydraulic Mining in California—No. 18, 193. Our selves; The Sonora Process; The Patent Office at Fault; The California Water Company; The Black Hills; The "Whoooping" or Sand-Hill Crane; 201. Economy of the Vegetable Kingdom, 208. The Microscopical Society; Patents and Inventions, 209. General News Items, 212.

ILLUSTRATIONS.—The District Telegraph, 193. The "Whoooping" or Sand-Hill Crane; 201. Economy of the Vegetable Kingdom, 208.

CORRESPONDENCE.—Mexican Mines; Australian Notes, 194.

SCIENTIFIC PROGRESS.—What are Bacteria? Sulphur as a Fire Extinguisher; The Wisdom of the Egyptians; A New Reaction of Essence of Mint; Oxygen in Hydrogen; New Microscopic Telescope; An Experiment with Silver; Cloud Observations, 195.

MECHANICAL PROGRESS.—Aluminum—Its Use and Preparation; To Form Perfect Squares; Iron and its Uses in Building; Distribution of Steam; Condensation in Steam Cylinders, 195.

MINING STOCK MARKET.—Thursday's sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 196.

MINING SUMMARY.—From the various counties in California, Nevada, Idaho and Utah, 196-7.

USEFUL INFORMATION.—How to Treat a Watch; Securing Safety in the Use of Steam Boilers; An Appropriate Emblem; Rubber Joints; Glue to Resist Fire; Varnish for Metallic Surfaces, 199.

GOOD HEALTH.—Take Good Care of your Servants; Tincture of Arnica Poisonous to the Skin; Sleeplessness, 194.

DOMESTIC ECONOMY.—Salads and Dressings; To Take out Bruses in Furniture; Home Repairs of Plastered Walls; Apple Snow; White Cake, 199.

POPULAR LECTURES.—Economy of the Vegetable Kingdom, 208.

MISCELLANEOUS.—The Microscopical Society, 194. New Combination Snuffs; Hardness of Wood; Ancient Progress in Tin Manufacture; Cabinet Making a Fine Art; Amateur Engine Building; Underground, 198. The Patent Law of the Republic of Chili; Gelatine; Frozen Quicksilver; Here and There; On the Motive Power of Dinosaurs, 201. U. S. Mining Laws, 202-3-4-5. Interesting Analogies in Nature, 208. California Railroad Items; Agricultural Items, 209.

Ourself.

It is not often that we take occasion to speak of ourselves, preferring to let the paper stand on its own merits; but this week we desire to call the attention of our readers to the double sheet edition of this issue. We have had numerous demands from different localities for the mining laws of the United States and accordingly have issued a supplement containing such information in this direction as the miners need. Every miner should carefully study these laws and understand them. The instructions of the Commissioners are given which gives the interpretation put upon the law by the Land Office. Some who read these laws for the first time will doubtless find there information of great value which may make a great difference to them in dollars and cents.

Our columns are so crowded from time to time that we occasionally find it necessary to issue a double sheet to relieve this pressure. As often as we are sufficiently provided with good reading and advertising matter, this double sheet edition will be printed. We have been giving, and will continue to give, a large amount of information to the mining and industrial public, and we hope, our readers will appreciate our endeavors. The Mining and Scientific Press is the recognized leading representative of the mining interests, and as such has been, we hope, a benefit to the coast. We shall continue to do all we can to maintain this position and only need the continued co-operation of the mining public to carry out our endeavors. The paper goes into every mining town and camp on the Pacific coast, and besides the general news of the day, every issue contains information of interest to the mining community, worth far more than the terms of subscription.

A fine prospect for quicksilver has recently been found about three miles southwest of Lower Lake.

The Sonora Process.

Working Rebellious Ores.

The process of working silver ores generally known as the "Sonora Process," was introduced by Mr. E. B. Smith, in Sonora, Mexico, in 1869, and since that time has been in use by that gentleman at the hacienda La Aguja. So marked and uniform has been its success that it has been adopted by every other hacienda in Sonora. The process is especially adapted to the treatment of rebellious ores; that is, all sulphuretted ores that require desulphurization and chlorination to allow the silver to admit of smelting.

The ore is prepared by roasting in a reverberatory furnace, reducing the silver and base metals to a chloride. The ore is then charged into boxes prepared with a false bottom, and is then luxuriated with water until the chlorides of the base metals are dissolved and washed out. A solution of hyposulphite of lime is then turned on the ore, which dissolves the chloride of silver. This silver, in solution, is then drawn off into tanks, and the silver precipitated by sulphide of lime. After the precipitation of the silver the resulting liquor is a hypersulphite, which is drawn off and pumped back into the ore tanks, to serve again as a solvent of the silver.

The precipitated silver is drawn off, strained and pressed, and then roasted in a small reverberatory furnace to burn off the sulphur, then and melted in crucibles with iron, or cupel furnaces with lead.

The advantages gained by this means are: 1st. The greater reduction of cost in the building of reduction works. 2d. The economy of power, as no machinery is used except the stamps for pulverizing the ore. 3d. Economy of crushing, as much coarser screens can be used in the batteries. 4th. Simplicity and certainty of results. 5th. Larger percentage of silver obtained than by any other economical means. 6th. No patent, no royalty, and no machinery.

Much depends upon the proper construction of the furnaces so as to economize fuel and produce the most perfect chlorination, and then on the skill and faithfulness of those in charge of the roasting. The construction of the works should be under the charge of some one thoroughly familiar with the process, so as to arrange all the appliances with a view to convenience and economy in the handling of the ores; but when once so constructed an intelligent worker in ores can soon familiarize himself with all the various manipulations which the ore goes through. It takes from one-quarter to one-half a cord of wood for roasting. The screens used generally are No. 24, so each stamp can crush a great deal more ore per day than when screens from No. 40 to 60 are used. The cost of working by this process of course varies with the locality, price of wood, etc. At Mr. Smith's hacienda, with a ten-stamp mill, if running steadily the cost is from \$10 to \$13 per ton of ore.

This process is now generally used in Sonora, but we do not know that it was ever introduced here. In Sonora they have used the patio, pans, and all other means, but have thrown them out, and now use this process with good results. No chemicals are used except salt and sulphur. Mr. Smith's mill has been a sort of custom mill for some time, and has worked all classes of ores successfully. The silver comes out generally about 900 fine, although it has been produced as high as 960. The process is specially adapted to rebellious silver-bearing ores, and we hope some of our readers may try it here. It appears admirably adapted for miners who do not want to erect large and expensive works. Mr. Smith, who is at present at 439 Bush street, in this city, will give all the desired information should any one feel interested in hearing more details of the matter.

The Patent Office at Fault.

We have entertained a high regard for the present Commissioner of Patents, and sincerely hoped that the patent office would suffer no detriment in his keeping. But circumstances compel us to complain of a portion of his machinery which seems to be terribly out of order. Of course we refer to what is known as the Philosophical Division, a class that is kept constantly in arrears. The simplest case falling within this class is kept under advisement for months, while the examiners in other classes do not require as many weeks to dispose of the most difficult and complicated machinery. In fact many of the cases, we are informed, are kept closely up. Why is this difference? We call the special attention of the honorable Commissioner to the fact that an inventor of electric signals for railroads filed his application in December, and on the 12th March was placed in interference with an application filed September 20th, 1873. Why was this latter case allowed to lie so long in the examiner's room, as a trap to catch unsuspecting parties who subsequently pay their money into the office and file their applications in good faith? We hope Commissioner Thatcher may be able to explain.

The California Water Company.

This company occupy the dividing ridge between the south and middle forks of the American river. The company is incorporated with a capital stock of \$10,000,000; principal place of business, Georgetown, El Dorado county. The officers are as follows: James S. Pierce, President; H. S. Bradley, Superintendent; H. J. McKusick, Superintendent of mining department, and C. H. Jones, Superintendent of water sales department. The company has 235 miles of ditches and iron pipe, covering 300 miles square of mining ground, and embracing the heavy gravel deposits of Mount Gregory, Tipton hill, Mameluque hill, Jones hill, Bottle hill, Fort hill, Buffalo hill, Five Cent hill, Pilot hill, etc., and the seam and surface diggings of Georgetown, Georgia slide, Spanish dry diggings, Greenwood, Johnstown, American Flat, Spanish Flat, Kelsey's, St. Lawrenceburg, and also many quartz mines, including the Clipper, the Woodside, the St. Lawrence, the Taylor, the Cedarberg, the Sliger, etc. The main supply ditch for this extensive region has a capacity of 4,000 inches, and its sources of supply are inexhaustible.

The company are now engaged in mining or selling water in most of the above named localities. For the past three years they have expended large amounts of money in extending and improving their ditches, acquiring mining claims, timber land, etc. But mining and water selling will by no means limit the scope of this company's operations. The main ditch, before arriving at the mineral belt where it is distributed, passes through some 200 square miles of valuable timber. Upon the line of the ditch are numerous falls, affording ample power for manufacturing lumber without a waste of water. A Vume to Sacramento is projected and surveys already commenced. By this means large amounts of lumber can be transported cheaply, and the water which conveys it be applied to irrigation directly in the neighborhood of the city.

It is also proposed to furnish water to Sacramento under pressure. Surveys and estimates for this project are now in progress. Sacramento is situated at the head of tidewater. If furnished with cheap water power the city would soon develop a variety of manufacturing interests. The California water company expect to be able to supply the city with an abundance of water in such a manner that it may be used for power and not be lost, but still supply the city in the same manner as if the power had not been used. The benefit to Sacramento of such an arrangement will of course be incalculable. The American river will never answer for this purpose, because it is too intermittent—in summer it is thick and sluggish, in winter it is unmanageable.

The company also intend to take steps to inaugurate agricultural prosperity on the divide. Notwithstanding all that has been said concerning the advantages and capabilities of the foothills, agriculture in the mountains has not flourished. Notwithstanding the quality of the fruit raised there, its abundance with the aid of a little certain irrigation, established tests concerning profits on fruits, nuts, grapes, berries, wine, there is something wanting which still prevents earnest and capable men of good business capacity from taking hold of agriculture in the mountains. But give men an assurance of water to irrigate from ten to forty acres for every five or six hundred acres of grazing or vineyard or nut tree land owned—the means, in short, of carrying on diversified agriculture, and before many years run by there will be a reflex of farming population instead of the continued depopulation of the mountain countries.

It should be understood that the California water company has only commenced to do that which is in process of execution, the benefits from which cannot be anticipated before the plan on which the organization is based shall have been further carried out. The company's business is already becoming remunerative.

Details of their mining operations, with facts and figures, will soon be published in the Press. The report on the property of this company, by Amos Bowman, recently issued, was the most exhaustive report of the kind ever published on this coast.

COPPER.—We learn from Jas. Lewis & Sons monthly Liverpool report on ores and metals that the market for copper is dull. During February the market for Chile bar copper was even more inanimate than during the previous month. At present the prices in Liverpool do not cover the cost of Chile with even a moderate commission. Quotations on the 1st of March were, bars, £82 to £82 10 s. for good ordinary brands, and £84 10 s. for special brands; ore and regains 16 s. to 16 s. 9d per unit. Stocks of West Coast produce were estimated in 12,838 tons pure against 12,242 tons on 1st ultimo.

The Shasta Courier speaks very hopefully of the future of that county. New mines are being taken up, and the water rights and other means of making the mineral resources available are being rendered and put in shape for future use.

The Black Hills.

The "Black Hills excitement" instead of being on the wane seems to be on the increase at present, and parties are talking of going there from every direction. We notice advertisements in the San Francisco daily papers, by which it seems an expedition is being formed here, and similar expeditions are being organized elsewhere. Reports from the Black Hill country are however very contradictory and unsatisfactory, but this only seems to excite the nomadic miners still more.

Some men have come into Cheyenne bringing rich specimens of placer gold, silver quartz and plumbago, lead and copper, and glowing reports of the country. They report diggings worth 15 cents to \$1 per pan, plenty of water, game, timber, etc. These men propose returning to the hills about the middle of April as well as the company from here.

Notwithstanding the fact that the Government has prohibited miners from entering the reservation there is no doubt that there will be a big rush there this spring. The following is General Sherman's order to General Ord:

The President directs the following to be made public: All expeditions into that portion of Indian territory known as the Black Hills country, must be prevented so long as the present treaty exists. Efforts are now being made to arrange for the extinguishment of the Indian title, and all proper means will be made to accomplish that end. If, however, the steps which are to be taken toward the opening of the country to settlement fail, those persons at present within that Territory must be expelled. By command of General Sherman.

WM. D. WHITTELL, Asst. Adj't-General.

It is now stated, however, that the Sioux are willing to relinquish their claims to the country for a consideration because they know that the whites will eventually get in there anyhow, and the Indians want to make a treaty with the Government before this happens. The Sioux City Journal of March 20th, states it has received information that President Grant has taken decided steps looking to a speedy opening of the Black Hills; that the Secretary of War and other members of the Cabinet are heartily in sympathy with the movement; that the Indians are willing to dispose of their interest in that country, and that Mr. Collins, of Helena, Ill., an old friend of the President, has been commissioned by him to proceed West and take to Washington a number of representative Sioux, to carry out the desired negotiations. This has not been made public, though some allusion to the matter has been telegraphed, so the fact will soon be developed, and it is thought that by the time the companies now organizing are ready to start, the opposition of the Government will be removed.

It is also stated that Secretary Delano has taken steps to bring to Washington a delegation of the Sioux for the purpose of negotiating the extinguishment of their right to the Black Hills country. Another report is that the treaty of the United States with the Sioux Indians was never ratified by Congress, and would not stand if tested. It strikes us however, that if this is so, and the present were insisted on, it would carry on an Indian war with good reason.

The opinion expressed by many, with relation to the whole Black Hill business, is that it is fostered and increased by parties interested in outfitting miners, and carrying on freight and other business. Reports are so very contradictory and vague that it is difficult to judge which are true. It will of course be settled this spring, however, for some will surely go. Those miners who have now paying claims will be foolish to leave them to go on a "wild goose chase" to the Black Hills or any other new country. Still, we do not believe that the Government will be able to keep prospectors out with its whole army. They have been in there already in spite of all orders to the contrary, and if they become convinced that the gold is there, all the proclamations in the world will not keep them out.

RUBBER PAINT.—We gave in our issue of February 13th some details of the manufacture of rubber paint, by the Pacific Rubber Paint company, whose advertisement will be found in another column. As the name indicates the paint is formed by a chemical combination of rubber with oil paints, which is done in such a manner that the resultant compound is so elastic as to preclude the possibility of cracking, and give a gloss, like varnished work. This paint is now being largely introduced on this coast and gives general satisfaction, as numerous testimonials show. An extensive factory has been established here, the facilities of which have lately been increased.

UNITED STATES MINING LAWS.—In accordance with the request of many of our subscribers, we publish in this issue of the Press, the United States mining laws. We give the United States Mining Law of May 10th, 1872, with the instructions of the Commissioner of the Land Office; also those parts of U. S. Mining Law of July 26th, 1866 and July 9th, 1870, that were not repealed by the Act of May 10th, 1872. We have made notes in the body of the law referring to such amendments as have been made since the passage of the Act, and giving briefly the tenor of the amendment.

The Patent Law of the Republic of Chile.

We publish the following law for the benefit of inventors on this coast and the Atlantic States. It becomes of more immediate importance in view of the approaching Industrial Exhibition in Chile, which opens in September next. Further information can be had on application to this office:

"Art. 1. The author or inventor of an art, manufacture, machine, instrument, preparation or any improvement upon any such thing, who may wish to enjoy the exclusive proprietorship of his discovery or invention, granted him by the 152d article of the Constitution, must make application to the Minister of the Interior, soliciting a patent which shall secure him such proprietorship, accompanying his petition with a faithful, clear and accurate description of his invention or discovery, together with an affidavit that it is his his own discovery or invention, and that it is unknown in the country; and he must at the same time present samples, or drawings, or models, according to the requirements of the case, to illustrate his claim."

"Art. 2. The Minister of the Interior will then appoint a commission of one or more experts to inquire into the matter, and to report to him as to the originality of the discovery or invention; requiring such commission to swear, in the presence of the petitioner, to faithfully execute the inquiry, and during all the time allowed patent privileges by this law, to keep religiously secret all information communicated to them during the inquiry."

"Art. 3. Upon the verification of the claims of the petitioner by this commission, the President of the Republic will order a patent issued to him, giving him the exclusive right in the country of the invention or discovery for a period of ten years, the patent being signed by the President and sealed with the seal of the Republic."

"Art. 4. Such patent shall be registered entire in a book kept for the purpose, in the office of the Minister of the Interior."

"Art. 5. Before receiving his patent, the petitioner will be required to present a certificate that he has paid into the Treasury of the Republic the sum of fifty dollars, and another, that he has deposited in the Patent Office of the country, samples, or drawings, or models, illustrative of his discovery or invention, together with a descriptive memorial, signed by every member of the commission as satisfactory to them, which memorial shall contain such a complete, minute and specific account of the invention or discovery as will distinguish it from all other known or need before in the country, and shall indicate the methods and principles of its application so plainly as to be understood by any intelligent person, and serve as a guide to its construction and use, so that the public may be benefited by it after the expiration of the term of duration of the patent."

"He will close and seal this memorial in the presence of the commission, and write upon its envelope the title and object of the patent, affirming that he has faithfully complied with the requirements of this law, and the commissioners will subscribe it. During the period of his patent, the patentee may inspect this sealed envelope whenever he pleases, with a view of seeing that its seals are as he left them."

"Art. 8. Inventions, arts, or discoveries, known or need in other countries, if not known or used in Chile, may obtain patents in the same manner, and under the same conditions, as discoveries or inventions made in the country, though for a time not exceeding eight years, according to the utility and difficulty of the enterprise, at the discretion of the Minister of the Interior. Mere change of form or proportion of a machine is not patentable."

"Art. 9. A patent right may be sold or transferred; but to do so, the patentee must notify the Minister of the Interior of his wish to do so, setting forth the reasons for the same. If those reasons are judged valid, a note of the fact is made in the register of patents; if not, proceedings may be commenced to annul the patent."

"Art. 10. Any person other than the patentee, who shall construct patented articles by the same method which characterizes and constitutes the patent, shall be liable to a fine of not less than one hundred nor more than one thousand dollars, shall forfeit all such articles already made, and all machinery and apparatus used in making them."

"Art. 11. Any patent obtained by false declarations or statements, as by persons pretending to be the inventors who are not, or that it is not known or in use in Chile when it is, shall be immediately annulled, and the patentee charged the costs of the investigation, and fined not less than one hundred nor more than one thousand dollars, or imprisoned not less than three months nor more than one year."

"Art. 13. Patents may be obtained for the whole Republic, or for one or more departments."

"Art. 14. In all cases of granting patents, a reasonable time will be allowed for the establishing and putting in working order of the invention or thing patented, after which the time of the patent privilege will commence."

"Art. 15. If, at the expiration of the time allowed for the establishment of the enterprise, it shall not have been so established and set at work, the patent shall become null and void; and the same, if, after its establishment, it shall be abandoned for one year, or if its pro-

ducts become inferior in quality or different in character from the samples or models deposited in the Patent Office."

"Art. 16. Nothing in this law shall affect the existing laws of the Republic, relative to the rights of miners, or to the copyrights of authors."

As the present interest in this matter is almost entirely due to the prospect which the Exposition offers to inventors and introducers, we call attention to this fact, that, to protect their rights under this law, no copying or taking of drawings of machinery or other article on exhibition will be allowed without authority of its proprietor. Even the Government can only take photographic or similar views of such articles.

Gelatine.

The interesting and singular fact appears that millions of dollars cover the value of the gelatine industry in this country, and this value is said to be still greater in Europe. The purest form of commercial gelatine is known as isinglass, the best being prepared from the air-bladders and sounds of three or four species of sturgeon. These tissues are cleansed, dried

THE "WHOOPIING" OR SAND-HILL CRANE.

and scraped, forming what is termed leaf isinglass, or they are twisted into various forms called long and short staple, or folded into packages called book isinglass.

The Russian isinglass has always held the highest rank in the market, but its manufacture is very simple. The swimming bladders of the fish are first placed in hot water, carefully deprived of adhering blood, cut open longitudinally and exposed to the air, with the inner delicate silvery membrane upward. When dried, this fine membrane is removed by heating and rubbing, and the swimming bladder is then made into the forme desired.

Machinery is employed to cut isinglass into the delicate filaments in which it is usually sold. A solid gelatine, in thin plates and eticage, is manufactured in large quantities in France, to answer the purpose of isinglass. The best is transparent, and is prepared from the gelatine of bones by digestion in dilute hydrochloric acid and long boiling in water. It is much cheaper than the first described article, as well as decidedly inferior. The same may be said of another variety, known as opaque gelatine, which is prepared from the cuttings of skins.

Of all metals known, silver is the best electrical conductor.

Frozen Quicksilver.

According to the *New Northwest* there has been somewhat of cold weather in Montana this winter. A correspondent of that paper writes: "Your favor of the 10th of January is at hand, and inquiries answered herewith. On the evening of January 8th, several persons being in my store, and the spirit thermometer registering '35 degrees below,' the remark was made that quicksilver would congeal at 3 degrees lower. I requested my clerk, Mr. Stolte, to thoroughly cleanse a glass tumbler and partially fill it with quicksilver. We then exposed the glass of mercury and the spirit thermometer on the roof of the fire-proof, on the north side of the store, giving them as nearly equal exposure as possible. An hour after, the thermometer marked 38 degrees below, but the quicksilver still remained unchanged. At 9:20 p. m. the thermometer stood 40 degrees below; still the quicksilver was free, but terribly cold. At 9:40 p. m. the spirit indicated 41 degrees below; the quicksilver was hardening on the outside. A few minutes later the thermometer stood 42 degrees below. I picked up the tumbler of quicksilver, and, to my astonish-

Whooping Crane.

The whooping crane or sand-hill crane, so familiar on this coast, breeds from California northward to the Arctic regions, whence it resumes southward early in autumn, and soon arrives in the regions of the United States, from North Carolina to Texas, and thence westward to the Rocky mountains, and remains throughout the winter. In the Middle States, east of the Alleghanies, it is very rarely seen, and thence eastward to Maine it is unknown, all its migrations being performed far inland. While migrating it travels both by day and night, and in total disregard of the character of the weather, its power of flight enabling it to resist the force of heavy gales. Thirty or forty form a flock, which is sometimes arranged in an acute-angled triangle, sometimes in a long line, and at others with an extended front, and sometimes flying in apparent disorder, each bird sounding his loud note in succession, as upon all occasions of alarm.

The middle of October or beginning of November is the period of the arrival of this species in the United States, and the end of April or beginning of May of its departure for the North. They here frequent the edges of large ponds supplied with rank herbage, on fields or savannas, now in swampy woods, and again on extensive marshes. The interior of the country and the neighborhood of seashores suit them equally well, so long as the temperature is sufficiently high. Both the old and the young may be seen digging through the mud before the rains have begun to cover the shallow ponds. They work assiduously with their bills, and succeed in uncovering the roots of the great water-lily, which often run to a depth of two or three feet. Several cranes operate at the same root and devour it together when obtained. They may then be approached easily and a number killed at a single shot. When this description of food fails they resort to the fields, to devour corn, peas, sweet potatoes and cotton seeds, and in the wet fields, seize on water insects, toads and frogs, and occasionally a mole, a meadow-mouse, or a snake, but not upon fish, as is believed. They feed only during the day.

Though these birds may be easily killed while intent upon exhuming their food, their sense of sight and hearing are so acute, and their wariness is so great, that it requires the practice of much adroitness to approach them. They are on the alert the moment a man appears, though a fourth of a mile distant; and, if not seen, the snapping of a twig beneath his feet, or the closing of a gate behind him, is sufficient to challenge their vigilance. They observe his motions with unerring precision. Mr. Audubon says he would soon undertake to catch a deer by fair running as to shoot one of these cranes which had observed him. When wounded they are capable of inflicting severe injury upon an unwary sportsman. Wilson states that one of them has even been known to drive his bill through a man's hand at such a time. The young are more numerous than the old. They are killed both for their flesh, which many relish, and for their beautiful long feathers, of which fans and fly-brushes are sometimes made.

In some regions, these birds leave their feeding grounds an hour before sunset, and silently repair to the interior of a highland forest, where six or seven of them alight on the branches of a lofty tree to roost. Here, after dressing their feathers for half an hour, they crouch in the manner of wild turkeys, and when there is moonlight may then be shot. In other regions they roost in the midst of tall grasses, cat-tails and other plants, near the marshes, selecting a dry hillock, upon which they stand on one foot, the other being drawn under the body, while the head is thrust beneath the broad feathers of the shoulder. In captivity they become gentle, and feed on grain and other vegetables, though they are occasionally mischievous, and wantonly pick and maim chickens and other poultry. They probably do not attain their full size nor perfect plumage before they are four or five years old.

On the Motive Power of Diatoms.

HERE AND THERE.—In New York city we are told there are thousands of men unemployed, and that so great is the destitution that the gangs of men employed on street work are changed frequently, in order to keep the wolf from the door of starving families. How different this from what is seen in San Francisco and this State. Our banks are plethoric with money, the genuine article of silver and gold. Our mines are turning out gold and bullion in quantities such as were never known before. Our fields are everywhere green and luxuriant with fruit, grass or grain. Our farms and mines afford abundant employment for labor at remunerative prices. The condition of our savings banks indicates a condition of prosperity among depositors which is truly gratifying to record. Our immigration is large and constantly increasing. Altogether, California appears to be entering upon a most prosperous period of her history. Between our valuable export productions of wheat, wool, wine tobacco, cotton and the precious metals, our source of wealth are really fabulous.

Professor Leidy, in some remarks on the moving power of diatoms, desmids, and other algae, stated that, while the cause of motion remains unknown, some of the uses are obvious. The power is considerable, and enables these minute organisms, when mingled with mud, readily to extricate themselves and rise to the surface, where they may receive the influence of light and air. In examining the surface mud of a shallow rain water pool, in a recent excavation in brick clay, he found little else but an abundance of minute diatoms. He was not sufficiently familiar with the diatoms to name the species, but it resembled *navicula radiosa*. The little diatoms were very active, gliding hither and thither, and knocking the quartz and grains about. Noticing the latter, he made some comparative measurements, and found that the naviculae would move grains of sand as much as twenty-five times their own superficial area, and probably fifty times their own bulk and weight, or perhaps more.

U. S. MINING LAWS

—AND—

Instructions Under the same by the Commissioner of the General Land Office.

[The following, together with blank forms and other pertinent information, will soon be printed and sold in pamphlet form, at this office.]

Mining Statute of May 10, 1872.

AN Act to promote the development of the mining resources of the United States.

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, That all valuable mineral deposits in land belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase, by the citizens of the United States, and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners, in the several mining districts, so far as the same are applicable and not inconsistent with the laws of the United States.

Sec. 2. That mining claims upon veins or lodes of quartz or other rock in place, bearing gold, silver, iron, lead, tin, copper, or other valuable deposits heretofore located, shall be governed, as to length along the vein or lode, by the customs, regulations, and laws in force at the date of their location. A mining claim located after the passage of this act, whether located by one or more persons, may equal, but shall not exceed, one thousand five hundred feet in length along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. No claim shall extend more than three hundred feet on each side of the middle of the vein at the surface, nor shall any claim be limited, by any mining regulation, to less than twenty-five feet on each side of the middle of the vein at the surface, except where adverse rights existing at the passage of this act shall render such limitation necessary. The end lines of each claim shall be parallel to each other.

Sec. 3. That the locators of all mining locations heretofore made, or which shall hereafter be made, on any mineral vein, lode, or ledge, situated on the public domain, their heirs and assigns, where no adverse claim exists at the passage of this act, so long as they comply with the laws of the United States and the State, Territorial, and local regulations, not in conflict with said laws of the United States, governing their possessory title, shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their location; and of all veins, lodes, and ledges, throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of said surface locations: *Provided*, that their right of possession to such outside parts of such veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward as aforesaid, through the end-lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of said veins or ledges. *And, provided further*, that nothing in this section shall authorize the locator or possessor of a vein or lode which extends, in its downward course, beyond the vertical lines of his claim, to enter upon the surface of a claim owned or possessed by another.

Sec. 4. That where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within three thousand feet from the face of such tunnel, on the line thereof not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface; and locations on the lines of such tunnel of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, shall be invalid; but failure to prosecute the work on the tunnel for six months shall be considered as an abandonment of the right to all undiscovered veins on the line of said tunnel.

[NOTE.—By an Act of Congress approved March 1st, 1873, the 5th section of this Act was amended so that the time for the first annual expenditure on claims located prior to the passage of the Act, was extended to June 10th, 1874. Again on June 6th, 1874, the 5th section of the Act of May 10th, 1872, was amended by Congress so that the time for the first annual expenditure on claims located prior to the passage of said Act, was extended to January 1st, 1875. By this legislation the requirements of the fifth section of the mining Act of May 10, 1872, and the Amendment Act of March 1st, 1873, were changed by extending the time for the first annual expenditure upon claims located prior to May 10th, 1872, to the 1st day of January, 1875. The requirement in regard to expenditures located since May 10th, 1872, were in no way changed by these amendatory acts.—EDMONT.]

Sec. 5. That the miners of each mining district may make rules and regulations, not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims, located by reference to some natural object or permanent monument, as will identify the claim. On each claim located after the passage of this act, and until a patent shall have been issued therefor, not less than one hundred dollars worth of labor shall be performed, or improvements made during each year. On all claims located prior to the passage of this act, ten dollars worth of labor shall be performed or improvements made each year for each one hundred feet in length along the vein, until a patent shall have been issued therefor; but where such claims are held in common, such expenditure may be made upon any one claim; and upon a failure to comply with these conditions, the claim or mine upon which such failure occurred shall be opened to relocation in the same manner as if no location of the same had ever been made: *Provided*, that the original locators, their heirs, assigns, or legal representatives, have not resumed work upon the claim after such failure and before such location. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required by this act the co-owners who have performed the labor or made the improvements may, at the expiration of the year, give such delinquent co-owner personal notice in writing, or notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days, and if, at the expiration of ninety days after such notice in writing or by publication, such delinquent should fail or refuse to contribute his proportion to comply with this act, his interest in the claim shall become the property of his co-owners who have made the required expenditures.

Sec. 6. That a patent for any land claimed and located for valuable deposits, may be obtained in the following manner: Any person, association, or corporation, authorized to locate a claim under this act, having claimed, and located a piece of land for such purposes, who has, or have, complied with the terms of this act, may file in the proper land office an application for a patent, under oath, showing such compliance, together with a plat and field-notes of the claim or claims in common, made by or under the direction of the United States Surveyor-general, showing accurately the boundaries of the claim or claims, which shall be distinctly marked by monuments on the grounds, and shall post a copy of such plat, together with a notice of such application for a patent, in a conspicuous place on the land embraced in such plat, previous to the filing of the application for a patent, and shall file an affidavit of at least two persons, that such notice has been duly posted as aforesaid, and shall file a copy of said notice in such land office, and shall thereupon be entitled to a patent for said land in the manner following: The Register of the land office, upon the filing of such application, plat, and field-notes notices, and affidavits, shall publish a notice that such application has been made, for the period of sixty days, in a newspaper to be by him designated as published nearest to said claim; and he shall also post such notice in his office for the same period. The claimant, at the time of filing his application, or at any time thereafter, within the sixty days of publication, shall file with the Register a certificate of the United States Surveyor-general that five hundred dollars worth of labor has been expended, or improvements made upon the claim by himself or grantors; that the plat is correct, with such further description by such reference to natural objects or permanent monuments as shall identify the claim, and furnish an accurate description to be incorporated in the patent. At the expiration of the sixty days of publication, the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during said period of publication. If no adverse claim shall have been filed with the Register and the Receiver of the proper land office at the expiration of the sixty days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists, and thereafter no objection from third parties to the issuance of a patent shall be heard, except it be shown that the applicant has failed to comply with this act.

Sec. 7. That where an adverse claim shall be filed during the period of publication, it shall be upon oath of the person or persons making the same, and shall show the nature, bound-

aries, and extent of such adverse claim; and all proceedings, except the publication of notice, and making and filing of the affidavit thereof, shall be stayed until the controversy shall have been settled or decided by a Court of competent jurisdiction, or the adverse claim waived. It shall be the duty of the adverse claimant, within thirty days after filing his claim, to commence proceedings in a court of competent jurisdiction, to determine the question of the right of possession, and prosecute the same with reasonable diligence to final judgment; and a failure to do so shall be a waiver of his adverse claim. After such judgment shall have been rendered, the party entitled to the possession of the claim, or any portion thereof, may, without giving further notice, file a certified copy of the judgment-roll with the Register of the land office, together with the certificate of the Surveyor-general that the requisite amount of labor has been expended, or improvements made thereon, and the description required in other cases, and shall pay to the Receiver five dollars per acre for his claim, together with the proper fees, whereupon the whole proceedings and the judgment-roll shall be certified by the Register to the Commissioner of the General Land Office, and a patent shall issue thereon for the claim, or such portion thereof as the applicant shall appear, from the decision of the court, to rightly possess. If it shall appear, from the decision of the court, that several parties are entitled to separate and different portions of the claim, each party may pay for his portion of the claim, with the proper fees, and file the certificate and description by the Surveyor-general, whereupon the Register shall certify the proceedings and judgment-roll to the Commissioner of the General Land Office, as in the preceding case, and patents shall issue to the several parties according to their respective rights. Proofs of citizenship under this act, or the acts of July twenty-sixth, eighteen hundred and sixty-six, and July ninth, eighteen hundred and seventy, in the case of an individual, may consist of his own affidavit thereof; and, in case of an association of persons unincorporated, of the affidavit of their authorized agent, made on his own knowledge, or upon information and belief, and in case of a corporation organized under the laws of the United States, or of any State or Territory of the United States, by the filing of a certified copy of their charter or certificate of incorporation; and nothing herein contained shall be construed to prevent the alienation of the title conveyed by a patent for a mining claim to any person whatever.

Sec. 8. That the description of vein or lode claims, upon surveyed lands, shall designate the location of the claim with reference to the lines of the public surveys, but need not conform therewith; but where a patent shall be issued as aforesaid, for claims upon unsurveyed lands, the Surveyor-general, in extending the surveys, shall adjust the same to the boundaries of such patented claim, according to the plat or description thereof, but so as in no case to interfere with or change the location of any such patented claim.

Sec. 9. That sections one, two, three, four and six of an act entitled "An Act granting the right of way to ditch and canal owners over the public lands, and for other purposes," approved July twenty-sixth, eighteen hundred and sixty-six, are hereby repealed, but such repeal shall not affect existing rights. Applications for patents for mining claims now pending may be prosecuted to a final decision in the General Land Office; but in such cases, where adverse rights are not affected thereby, patents may issue in pursuance of the provisions of this act; and all patents for mining claims heretofore issued under the act of July twenty-sixth, eighteen hundred and sixty-six, shall convey all the rights and privileges conferred by this act, where no adverse rights exist at the time of the passage of this act.

Sec. 10. That the act entitled "An Act to amend an act granting the right of way to ditch and canal owners over the public lands, and for other purposes," approved July ninth, eighteen hundred and seventy, shall be and remain in full force, except as to the proceedings to obtain a patent, which shall be similar to the proceedings prescribed by sections six and seven of this act for obtaining patents to vein or lode claims. But where said placer claims shall be upon surveyed lands, and conform to legal subdivision, no further survey or plat shall be required, and all placer mining claims hereafter located shall conform as near as practicable with the United States system of public land surveys and the rectangular subdivisions of such surveys, and no such location shall include more than twenty acres for each individual claimant; but where placer claims can not be conformed to legal subdivisions, survey and plat shall be made as on unsurveyed lands; *Provided*, That proceedings now pending may be prosecuted to their final determination under existing laws; but the provisions of this act, when not in conflict with existing laws, shall apply to such cases; *And, provided also*, That where, by the segregation of mineral land in any legal subdivisions, a quantity of agricultural land less than forty acres remains, said fractional portion of agricultural land may be entered by any party qualified by law, for homestead or pre-emption purposes.

Sec. 11. That where the same person, association, or corporation, is in possession of a placer claim, and also a vein or lode included within the boundaries thereof, application shall be made for a patent for the placer claim, with the statement that it includes such vein or lode, and in such case (subject to the provisions of this act and the act entitled "An Act to amend an act granting the right of way to ditch and canal owners over the public lands, and for other purposes," approved July ninth, eighteen hundred and seventy) a patent shall issue for the placer claim, including such vein or lode, upon the payment of five dollars per acre for such vein or lode claim, and twenty-five feet of surface on each side thereof. The remainder of the placer claim, or any placer claim not embracing any vein or lode claim, shall be paid for at the rate of two dollars and fifty cents per acre, together with all costs of proceeding; and where a vein or lode, such as is described in the second section of this act, is known to exist within the boundaries of a placer claim, an application for a patent for such placer claim, which does not include an application for the vein or lode claim, shall be construed as a conclusive declaration that the claimant of the placer claim has no right of possession of the vein or lode claim; but where the existence of a vein or lode in a placer claim is not known, a patent for the placer claim shall convey all valuable mineral and other deposits within the boundaries thereof.

Sec. 12. That the Surveyor-general of the United States may appoint, in each land district containing mineral lands, as many competent surveyors as shall apply for appointment to survey mining claims. The expenses of the survey of vein or lode claims, and the survey and subdivision of placer claims into smaller quantities than one hundred and sixty acres, together with the cost of publication of notices, shall be paid by the applicants, and they shall be at liberty to obtain the same at the most reasonable rates, and they shall also be at liberty to employ any United States Deputy Surveyor to make the survey. The Commissioner of the General Land Office shall also have power to establish the maximum charges for surveys and publication of notices under this act; and, in case of excessive charges for publication, he may designate any newspaper published in a land district where mines are situated, for the publication of mining notices in such district, and fix the rates to be charged by such paper; and to the end that the Commissioner may be fully informed on the subject, each applicant shall file with the Register a sworn statement of all charges and the fees paid by said applicant for publication and survey, together with all fees and money paid the Register and the Receiver of the Land office, which statement shall be transmitted, with the other papers in the case, to the Commissioner of the General Land Office. The fees of the Register and the Receiver shall be five dollars each for filing and acting upon each application for patent or adverse claim filed, and they shall be allowed the amount fixed by law for reducing testimony to writing—when done in the Land Office, such fees and allowances to be paid by the respective parties—and no other fees shall be charged by them in such cases. Nothing in this act shall be construed to enlarge or affect the rights of either party in regard to any property in controversy at the time of the passage of this act, or of the act entitled "An Act granting the right of way to ditch and canal owners over the public lands, and for other purposes," approved July twenty-sixth, eighteen hundred and sixty-six; nor shall this act affect any right acquired under said act; and nothing in this act shall be construed to repeal, impair, or in any way affect the provisions of the act entitled "An Act granting to A. S. Sutor the right of way and other privileges to aid in the construction of a draining and exploring tunnel to the Comstock lode, in the State of Nevada," approved July twenty-fifth, eighteen hundred and sixty-six.

Sec. 13. That all affidavits required to be made under this act, or the act of which it amendatory, may be verified before any officer authorized to administer oaths within the land district where the claims may be situated, and all testimony and proofs may be taken before any such officer, and, when duly certified by the officer taking the same, shall have the same force and effect as if taken before the Register and Receiver of the Land Office. In cases of contest as to the mineral or agricultural character of land, the testimony and proofs may be taken as herein provided, on personal notice of at least ten days, to the opposing party; or if said party cannot be found, then by publication of at least once a week for thirty days in a newspaper, to be designated by the Register of the Land Office as published nearest to the location of such land; and the Register shall require proof that such notice has been given.

Sec. 14. That where two or more veins intersect or cross each other, priority of title shall govern, and such prior location shall be entitled to all ore or mineral contained within the space of intersection; *Provided, however*, That the subsequent location shall have the right of way through said space of intersection for the purpose of the convenient working of the said mine; *And, provided also*, That where two or more veins unite, the oldest or prior location shall take the vein below the point of union including all the space of intersection.

Sec. 15. That where non-mineral land, not contiguous to the vein or lode, is used or occupied by the proprietor of such vein or lode for mining or milling purposes, such non-adjacent surface-ground may be embraced and included in an application for a patent for such vein or lode, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notices as are applicable under this act to veins or lodes; *Provided*, That no location hereafter made of such non-adjacent land shall exceed five acres, and payment for the same

not be made at the same rate as fixed by this act for the superficies of the lode. The owner of quartz mill or reduction works, not owning a mine in connection therewith, may also receive patent for his mill-site as provided in this section.

Sec. 16. That all acts and parts of acts inconsistent herewith are hereby repealed; *Provided*, that nothing contained in this act shall be construed to impair, in any way, rights or interests in mining property acquired under existing laws.

Approved May 10, 1872.

Instructions of the Commissioner.

Mineral Lands Open to Exploration, Occupation, and Purchase.

First. It will be perceived that the first section of said act leaves the mineral lands in the public domain, surveyed or unsurveyed, open to exploration, occupation, and purchase, by all citizens of the United States, and all those who have declared their intention to become such.

Status of Lode Claims Previously Located.

Second. By an examination of the several sections of the foregoing act, it will be seen that the status of lode claims located previous to the date thereof, is not changed with regard to their extent along the lode or width of surface, such claims being restricted and governed both as to their lateral and linear extent, by the State, Territorial, or local laws, customs, or regulations, which were in force in the respective districts at the date of such locations, in so far as the same did not conflict with the limitations fixed by the mining statute of July 26, 1866. (14 Stat., 251.)

Third. Mining rights acquired under such previous locations, are, however, enlarged by the act of May 10, 1872, in the following respect, viz: The locators of all such previously taken vein or lodes, their heirs or assigns, so long as they comply with the laws of Congress and the State, Territorial, or local regulations not in conflict therewith, governing mining claims, are invested by said act with the exclusive possessory right of all the surface included within the lines of their locations, and of all veins, lodes, or ledges, throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges, may so far depart from a perpendicular in their course upward as to extend outside the vertical side lines of such locations at the surface, it being expressly provided, however, that the right of possession to such outside parts of said veins or ledges shall be confined to such portions thereof as lie between vertical planes drawn downward from the end-lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of such veins, lodes, or ledges; no right being granted, however, to the claimant of such outside portion of a vein or ledge, to enter upon the surface location of another claimant.

Fourth. It is to be distinctly understood, however, that the law limits the possessory right to veins, lodes, or ledges, other than the one named in the original location, to such as are not adversely claimed at the date of said act of May 10, 1872, and that where such other vein or ledge was so adversely claimed at that date, the right of the party so adversely claiming in no way impaired by said act.

Fifth. From and after the date of said act of Congress, in order to hold the possessory right to a mining claim previously located and for which a patent has not been issued, the law requires that ten dollars shall be expended annually in labor or improvements, on each side of one hundred feet on the course of the vein or lode, until a patent shall have been issued therefor; but where a number of such claims are held in common upon the same vein or lode, the aggregate expenditure that would be necessary to hold all the claims, at the rate of ten dollars per hundred feet, may be made upon any one claim; a failure to comply with this requirement in any one year, subjecting the claim upon which such failure occurred to relocation by other parties, the same as if no previous location thereof had ever been made, unless the claimants under the original location shall have resumed work thereon, after such failure and before such relocation.

Sixth. Upon the failure of any one of several co-owners of a vein, lode, or ledge, which has not been patented, to contribute his proportion of the expenditures necessary to hold the claim or claims so held in ownership in common, the co-owners who have performed the labor, and made the improvements as required by said act, may at the expiration of the year, give such delinquent co-owner personal notice in writing or by notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days; and if, upon the expiration of ninety days after such notice in writing, or upon the expiration of one hundred and eighty days after the first newspaper publication of notice, the delinquent co-owner shall have failed to contribute his proportion to meet such expenditure or improvements, his interest in the claim by law passes to his co-owners, who have made the expenditures or improvements as aforesaid.

Patents for Veins or Lodes Heretofore Issued.

Seventh. Rights under patents for veins or lodes heretofore granted under previous legislation of Congress, are enlarged by this act, so as to invest the patentee, his heirs or assigns, with title to all veins, lodes, or ledges throughout their entire depth, the top or apex of which is within the end and side boundary lines of his claim on the surface as patented, extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of the claim at the surface. The right of possession to such outside parts of such veins or ledges to be confined to such portions thereof as lie between vertical planes drawn downward through the end-lines of the claim at the surface, so continued in their own direction that such planes will intersect such exterior parts of such veins or ledges, it being expressly provided, however, that all veins, lodes, or ledges, the top or apex of which lies inside such surface locations, other than the one named in the patent, which were adversely claimed at the date of said act, are excluded from such conveyance by patent.

Eighth. Applications for patents for mining claims pending at the date of the act of May 10, 1872, may be prosecuted to final decision in the General Land office, and where no adverse claims are affected thereby, patents will be issued, in pursuance of the provisions of said acts.

Manner of Locating Claims on Veins or Lodes After the Passage of the Act of May 10, 1872.

Ninth. From and after date of said act, any person who is a citizen of the United States, who has declared his intention to become a citizen may locate, record and hold a mining claim of fifteen hundred linear feet along the course of any mineral vein or lode subject to location; or an association of persons, severally qualified as above, may make joint location of such claim of fifteen hundred feet, but in no event can a location of a vein or lode made subsequent to the act exceed fifteen hundred feet along the course thereof whatever may be the number of persons composing the association.

Tenth. With regard to the extent of surface ground adjoining a vein or lode, and claimed as the convenient working thereof, the act provides that the lateral extent of locations of veins or lodes made after its passage shall in no case exceed three hundred feet on each side of the middle of the vein at the surface, and that no such surface rights shall be limited by any mining regulations to less than twenty-five feet on each side of the middle of the vein at the surface, except where adverse rights existing at the date of said act may render such limitation necessary, the end-lines of such claims to be in all cases parallel to each other.

Eleventh. By the foregoing it will be perceived that no lode claim located after the date of said act can exceed a parallelogram fifteen hundred feet in length by six hundred feet in width, and whether surface ground of that width can be taken, depends upon the local regulations or State or Territorial laws in force in the several mining districts; and that no such local regulations shall limit a vein or lode claim to less than fifteen hundred feet along the course thereof, whether the location is made by one or more persons, nor can surface rights be limited to less than fifty feet in width, unless adverse claims existing on the tenth day of May, 1872, render such lateral limitation necessary.

Twelfth. It is provided in said act that the miners of each district may make rules and regulations not in conflict with the laws of the United States, or of the State or Territory in

which such districts are respectively situated, governing the location, manner of recording, and amount of work necessary to hold possession of a claim. It likewise requires that the location must be so distinctly marked on the ground that its boundaries may be readily traced. This is a very important matter, and locators cannot exercise too much care in defining their locations at the outset, inasmuch as the law requires that all records of mining locations made subsequent to its passage, shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located, by reference to some natural object or permanent monument, as will identify the claim.

Thirteenth. The said act requires that no lode-claim can be recorded until after the discovery of a vein or lode within the limits of the ground claimed; the object of which provision is evidently to prevent the encumbering of the district mining records with useless locations before sufficient work has been done thereon to determine whether a vein or lode has really been discovered or not.

Fourteenth. The claimant should therefore, prior to recording his claim, unless the vein can be traced upon the surface, sink a shaft, or run a tunnel or drift, to a sufficient depth therein to discover and develop a mineral-bearing vein, lode, or crevice; should determine, if possible, the general course of such vein in either direction from the point of discovery, by which direction he will be governed in making the boundaries of his claim on the surface, and should give the course and distance as nearly as practicable from the discovery-shaft on the claim, to some permanent well-known points or objects, such, for instance, as stone monuments, blazed trees, the confluence of streams, point of intersection of well-known gulches, ravines, or roads, prominent buttes, hills, &c., which may be in the immediate vicinity, and which will serve to perpetuate and fix the locus of the claim and render it susceptible of identification from the description thereof given in the record of locations in the district.

Fifteenth. In addition to the foregoing data, the claimant should state the names of adjoining claims, or if none adjoin, the relative positions of the nearest claims; should drive a post or erect a monument of stones at each corner of his surface-ground, and at the point of discovery or discovery-shaft, should fix a post, stake, or board, upon which should be designated the name of the lode, the name or names of the locators, the number of feet claimed, and in which direction from the point of discovery; it being essential that the location notice filed for record, in addition to the foregoing description, should state whether the entire claim of fifteen hundred feet is taken on one side of the point of discovery, or whether it is partly upon one and partly upon the other side thereof, and in the latter case, how many feet are claimed upon each side of such discovery-point.

Sixteenth. Within a reasonable time, say twenty days after the location shall have been marked on the ground, notice thereof, accurately describing the claim in manner aforesaid, should be filed for record with the proper Recorder of the district, who will thereupon issue the usual certificate of location.

Seventeenth. In order to hold the possessory right to a claim of fifteen hundred feet of a vein or lode located as aforesaid, the act requires that until a patent shall have been issued therefor, not less than one hundred dollars worth of labor shall be performed or improvements made thereon during each year, in default of which the claim will be subject to relocation by any other party having the necessary qualifications, unless the original locator or his heirs, assigns, or legal representatives, have resumed work thereon after such failure and before such relocation.

Eighteenth. The importance of attending to these details in the matter of location, labor, and expenditure will be the more readily perceived when it is understood that a failure to give the subject proper attention, may invalidate the claim.

Tunnel Rights.

Nineteenth. The fourth section of the act provides that where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within three thousand feet from the face of such tunnel on the line thereof, not previously known to exist, discovered in such tunnel, to the same extent as if discovered from the surface; and locations on the line of such tunnel of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, shall be invalid, but failure to prosecute the work on the tunnel for six months shall be considered as an abandonment of the right to all undiscovered veins or lodes on the line of said tunnel.

Twentieth. The effect of this section is simply to give the proprietors of a mining tunnel, run in good faith, the possessory right to fifteen hundred feet of any blind lodes cut, discovered, or intersected by such tunnel, which were not previously known to exist, within three thousand feet from the face or point of commencement of such tunnel, and to prohibit other parties, after the commencement of the tunnel, from prospecting for and making location of lodes on the line thereof, and within said distance of three thousand feet, unless such lodes appear upon the surface, or were previously known to exist.

Twenty-first. The term "face," as used in said section, is construed and held to mean the first working face formed in the tunnel, and to signify the point at which the tunnel actually enters cover, it being from this point that the three thousand feet are to be counted, upon which prospecting is prohibited as aforesaid.

Twenty-second. To avail themselves of the benefits of this provision of law, the proprietors of a mining tunnel will be required, at the time they enter cover as aforesaid, to give proper notice of their tunnel location, by erecting a substantial post, board, or monument, at the face or point of commencement thereof, upon which there should be posted a good and sufficient notice, giving the names of the parties or company claiming the tunnel right; the actual or proposed course or direction of the tunnel; the height and width thereof, and the course and distance from such face or point of commencement to some permanent well-known objects in the vicinity by which to fix and determine the locus in manner heretofore set forth applicable to locations of veins or lodes, and at the time of posting such notice they shall, in order that miners or prospectors may be enabled to determine whether or not they are within the lines of the tunnel, establish the boundary lines thereof by stakes or monuments placed along such lines at proper intervals, to the terminus of the three thousand feet from the face or point of commencement of the tunnel; and the lines so marked will define and govern as to the specific boundaries within which prospecting for lodes not previously known to exist, is prohibited while work on the tunnel is being prosecuted with reasonable diligence.

Twenty-third. At the time of posting notice and marking out the lines of the tunnel as aforesaid, a full and correct copy of such notice of location, defining the tunnel claim, must be filed for record with the Mining Recorder of the district, to which notice must be attached the sworn statement or declaration of the owners, claimants, or projectors of such tunnel, setting forth the facts in the case; stating the amount expended by themselves and their predecessors in interest in prosecuting work thereon; the extent of the work performed, and that it is bona fide their intention to prosecute work on the tunnel so located and described with reasonable diligence, for the development of a vein or lode, or for the discovery of mines, or both, as the case may be.

Twenty-fourth. This notice of location must be duly recorded, and with the said sworn statement attached, kept on the recorder's files for future reference.

Twenty-fifth. By a compliance with the foregoing, much needless difficulty will be avoided, and the way for the adjustment of legal rights acquired in virtue of said fourth section of the act will be made much more easy and certain.

Twenty-sixth. This office will take particular care that no improper advantage is taken of this provision of law by parties making, or professing to make tunnel locations, ostensibly for the purposes named in the statute, but really for the purpose of monopolizing the lands lying in front of their tunnels to the detriment of the mining interests, and to the exclusion of bona fide prospectors or miners; but will hold such tunnel claimants to a strict compliance with the terms of the act; and as reasonable diligence on their part in prosecuting the work is one of the essential conditions of their implied contract, negligence or want of due diligence will be construed as working a forfeiture of their right to all undiscovered veins on the line of such tunnel.

Manner of Proceeding to Obtain Government Title to Vein or Lode Claim.

Twenty-seventh. By the sixth section of said act, authority is given for granting title for mines by patent from the government, to any person, association, or corporation having the necessary qualifications as to citizenship and holding the right of possession to a claim in compliance with law.

Twenty-eighth. The claimant is required in the first place to have a correct survey of his claim made under authority of the Surveyor-general of the State or Territory in which the claim lies; such survey to show with accuracy the exterior surface boundaries of the claim, which boundaries are required to be distinctly marked by monuments on the ground.

Twenty-ninth. The claimant is then required to post a copy of the plat of such survey in a conspicuous place upon the claim, together with notice of his intention to apply for a patent therefor, which notice will give the date of posting, the name of the claimant, the name of the claim, mine, or lode; the mining district and county; whether the location is of record, and if so where the record may be found; the number of feet claimed along the vein, and the presumed direction thereof; the number of feet claimed on the lode in each direction from the point of discovery, or other well-defined place on the claim; the name or names of adjoining claimants on the same or other lodes; or if none adjoin, the names of the nearest claims, etc.

Thirtieth. After posting the said plat and notice upon the premises, the claimant will file with the proper Register and Receiver a copy of such plat, and the field notes of survey of the claim, accompanied by the affidavit of at least two credible witnesses, that such plat and notice are posted conspicuously upon the claim, giving the date and place of such posting; a copy of the notice so posted to be attached to, and form a part of, said affidavit.

Thirty-first. Attached to the field notes so filed must be the sworn statement of the claimant that he has the possessory right to the premises therein described, in virtue of a compliance by himself (and by his grantors, if he claims by purchase) with the mining rules, regulations, and customs of the mining district, State, or Territory, in which the claim lies, and with the mining laws of Congress; such sworn statement to narrate briefly, but as clearly as possible, the facts constituting such compliance, the origin of his possession, and the basis of his claim to a patent.

Thirty-second. This affidavit should be supported by appropriate evidence from the Mining Recorder's office, as to his possessory right, as follows, viz: Where he claims to be a locator, a full, true, and correct copy of such location should be furnished, as the same appears upon the mining records; such copy to be attested by the seal of the Recorder, or if he has no seal, then he should make oath to the same being correct, as shown by his records; where the applicant claims as a locator in company with others, who have since conveyed their interests in the lode to him, a copy of the original record of location should be filed, together with an abstract of title from the proper Recorder, under seal or oath as aforesaid, tracing the co-locator's possessory rights in the claim to such applicant for patent; where the applicant claims only as a purchaser for valuable consideration, a copy of the location record must be filed, under seal or upon oath as aforesaid, with an abstract of title certified as above by the proper Recorder, tracing the right of possession by a continuous chain of conveyances from the original locutors to the applicant.

Thirty-third. In the event of the mining records in any case having been destroyed by fire, or otherwise lost, affidavit of the fact should be made, and secondary evidence of possessory title will be received, which may consist of the affidavit of the claimant, supported by those of any other parties cognizant of the facts relative to his location, occupancy, possession, improvements, etc.; and in such case of lost records, any deeds, certificates of location or purchase, or other evidence which may be in the claimant's possession, and tend to establish his claim, should be filed.

Thirty-fourth. Upon the receipt of these papers, the Register will at the expense of the claimant, publish a notice of such application for the period of sixty days, in a newspaper published nearest to the claim, and will post a copy of such notice in his office for the same period.

Thirty-fifth. The notices so published and posted must be as full and complete as possible, and embrace all the data given in the notice posted upon the claim.

Thirty-sixth. Too much care cannot be exercised in the preparation of these notices, inasmuch as upon their accuracy and completeness, will depend, in a great measure, the regularity and validity of the whole proceeding.

Thirty-seventh. The claimant, either at the time of filing these papers with the Register, or at any time during the sixty days publication, is required to file a certificate of the Surveyor-general that not less than five hundred dollars worth of labor has been expended or improvements made upon the claim by the applicant or his grantors; that the plat filed by the claimant is correct; that the field notes of the survey, as filed, furnish such an accurate description of the claim, as will, if incorporated into a patent, serve to fully identify the premises, and that such reference is made therein to natural objects or permanent monuments, as will perpetuate and fix the locus thereof.

Thirty-eighth. It will be the more convenient way to have this certificate indorsed by the Surveyor-general, both upon the plat and field notes of survey filed by the claimant as aforesaid.

Thirty-ninth. After the sixty days period of newspaper publication has expired the claimant will file his affidavit, showing that the plat and notice aforesaid remained conspicuously posted upon the claim sought to be patented during said sixty days publication.

Fortieth. Upon the filing of this affidavit the Register will, if no adverse claim was filed in his office during the period of publication, permit the claimant to pay for the land according to the area given in the plat and field notes of survey aforesaid, at the rate of five dollars for each acre and five dollars for each fractional part of an acre, the receiver issuing the usual duplicate receipt therefor; after which the whole matter will be forwarded to the Commissioner of the General Land Office and a patent issued thereon if found regular.

Forty-first. In sending up the papers in the case the Register must not omit certifying to the fact that the notice was posted in his office for the full period of sixty days, such certificate to state distinctly when such posting was done and how long continued.

Forty-second. The consecutive series of numbers of mineral entries must be continued, whether the same are of lode or placer claims.

Forty-third. The Surveyor-general must continue to designate all surveyed mineral claims as heretofore by a progressive series of numbers, beginning with lot No. 37 in each township; the claim to be so designated at date of filing the plat, field notes, etc., in addition to the local designation of the claim; it being required in all cases that the plat and field notes of the survey of a claim must, in addition to the reference to permanent objects in the neighborhood, describe the locus of the claim with reference to the lines of public surveys by a line connecting a corner of the claim with the nearest public corner of the United States surveys, unless such claim be on unsurveyed lands at a remote distance from such public corner; in which latter case the reference by course and distance to permanent objects in the neighborhood will be a sufficient designation by which to fix the locus until the public surveys shall have been closed upon its boundaries.

Adverse Claims.

Forty-fourth. The seventh section of the act provides for adverse claims; fixes the time within which they shall be filed to have legal effect, and prescribes the manner of their adjustment.

Forty-fifth. Said section requires that the adverse claim shall be filed during the period of publication of notice; that it must be on the oath of the adverse claimant; and that it must show the "nature," the "boundaries" and the "extent" of the adverse claim.

Forty-sixth. In order that this section of law may be properly carried into effect, the following is communicated for the information of all concerned.

Forty-seventh. An adverse mining claim must be filed with the Register of the same land office with whom the application for patent was filed, or in his absence with the Receiver, and within the sixty days' period of newspaper publication of notice.

Forty-eighth. The adverse notice must be duly sworn to before an officer authorized to administer oaths within the land district, or before the Register and Receiver; it will fully set forth the nature and extent of the interference or conflict; whether the adverse party claims as a purchaser for valuable consideration or as a locator; if the former, the original conveyance, or a duly certified copy thereof, should be furnished, or if the transaction was a mere verbal one he will narrate the circumstances attending the purchase, the date thereof and the amount paid, which facts should be supported by the affidavit of one or more witnesses, if any were present at the time, and if he claims as a locator he must file a duly certified copy of the location from the office of the proper recorder.

Forty-ninth. In order that the "boundaries" and "extent" of the claim may be shown, it will be incumbent upon the adverse claimant to file a plat showing his claim and its relative situation or position with the one against which he claims, so that the extent of the conflict may be the better understood. This plat must be made from an actual survey by a United States deputy surveyor, who will officially certify thereon to its correctness; and in addition there must be attached to such plat of survey a certificate or sworn statement by the surveyor as to the approximate value of the labor performed, or improvements made upon the claim of the adverse party, and the plat must indicate the position of any shafts, tunnels, or other improvements, if any such exist upon the claim of the party opposing the application.

Fiftieth. Upon the foregoing being filed within the sixty days as aforesaid, the Register, or in his absence the Receiver, will give notice in writing to both parties to the contest that such adverse claim has been filed, informing them that the party who filed the adverse claim will be required within thirty days from the date of such filing to commence proceedings in a court of competent jurisdiction, to determine the question of right of possession, and to prosecute the same with reasonable diligence to final judgment; and that should such adverse claimant fail to do so, his adverse claim will be considered waived, and the application for patent will be allowed to proceed upon its merits.

Fifty-one. When an adverse claim is filed as aforesaid, the Register or Receiver will indorse upon the same the precise date of filing, and preserve a record of the date of notifications issued thereon; and thereafter all proceedings upon the application for patent will be suspended, with the exception of the completion of the publication and posting of notices and plat, and the filing of the necessary proof thereof, until the controversy shall have been adjudicated in court, or the adverse claim waived or withdrawn.

Fifty-second. The proceedings after rendition of judgment by the court in such case are so clearly defined by the act itself as to render it unnecessary to enlarge thereon in this place.

Placer Claims.

Fifty-third. The tenth section of the act under consideration provides "that the act entitled 'An act to amend an act granting the right of way to ditch and canal owners over the pub-

lic lands, and for other purposes,' approved July 9, 1870, shall be and remain in full force, except as to the proceedings to obtain a patent, which shall be similar to the proceedings prescribed by sections six and seven of this act for obtaining patents for vein or lode claims, but where said placer claims shall be upon surveyed lands and conform to legal subdivisions, no further survey or plat shall be required, and all placer mining claims hereafter located shall conform, as nearly as practicable, with the United States system of public land surveys and the rectangular subdivisions of such surveys, and no such locations shall include more than twenty acres for each individual claimant; but where placer claims cannot be conformed to legal subdivisions, survey and plat shall be made as on unsurveyed lands," etc.

Fifty-fourth. The proceedings for obtaining patents for veins or lodes having already been fully given, it will not be necessary to repeat them here; it being thought that careful attention thereto by applicants and the local officers will enable them to act understandingly in the matter, and make such slight modifications in the notice, or otherwise, as may be necessary in view of the different nature of the two classes of claims, placer claims being fixed, however, at two dollars and fifty cents per acre, or fractional part of an acre.

Fifty-fifth. The twelfth and thirteenth sections of said act of July 9, 1870, read as follows:

Sec. 12. *And be it further enacted*, That claims, usually called "placers," including all forms of deposit, excepting veins of quartz, or other rock in place, shall be subject to entry and patent under this act, under like circumstances and conditions, and upon similar proceedings, as are provided for vein or lode claims: *Provided*, That where the lands have been previously surveyed by the United States, the entry in its exterior limits shall conform to the legal subdivisions of the public lands, no further survey or plat in such case being required, and the lands may be paid for at the rate of two dollars and fifty cents per acre: *Provided, further*, That legal subdivisions of forty acres may be subdivided into ten-acre tracts; and that two or more persons, or association of persons, having contiguous claims of any size, although such claims may be less than ten acres each, may make joint entry thereof: *And, provided further*, That no location of a placer claim, hereafter made, shall exceed one hundred and sixty acres for any one person or association of persons, which location shall conform to the United States surveys; and nothing in this section contained shall defeat or impair any bona fide pre-emption or homestead claim upon agricultural lands, or authorize the sale of the improvements of any bona fide settler to any purchaser.

Sec. 13. *And be it further enacted*, That where said person or association, they and their grantors, shall have held and worked their said claims for a period equal to the time prescribed by the statute of limitations for mining claims of the State or Territory where the same may be situated, evidence of such possession and working of the claims for such period shall be sufficient to establish a right to a patent thereto under this act, in the absence of any adverse claim: *Provided, however*, That nothing in this act shall be deemed to impair any lien which may have attached, in any way whatever, to any mining claim or property thereto attached prior to the issuance of a patent.

Fifty-sixth. It will be observed that that portion of the first proviso to said twelfth section, which requires placer claims upon surveyed lands to conform to legal subdivisions, is repealed by the present statute with regard to claims heretofore located, but that where such claims are located previous to survey, and do not conform to legal subdivisions, survey, plat, and entry thereof, may be made according to the boundaries fixed by local rules, but that where such claims do conform to legal subdivisions, the entry may be effected according to such legal subdivisions, without the necessity of further survey or plat.

Fifty-seventh. In the second proviso to said twelfth section, authority is given for the subdivision of forty-acre legal subdivisions into ten-acre lots, which is intended for the greater convenience of miners in segregating their claims, both from one another and from intervening agricultural land.

Fifty-eighth. It is held, therefore, that under a proper construction of the law, these ten-acre lots in mining districts, should be considered and dealt with, to all intents and purposes, as legal subdivisions, and that an applicant having a legal claim which conforms to one or more of these ten-acre lots, either adjoining or cornering, may make entry thereof, after the usual proceedings, without further survey or plat.

Fifty-ninth. In cases of this kind, however, the notice given of the application must be very specific and accurate in description, and as the forty-acre tracts may be subdivided into ten-acre lots, either in the form of squares of ten by ten chains, or of parallelograms five by twenty chains, so long as the lines are parallel and at right angles with the lines of the public surveys, it will be necessary that the notice and application state specifically what ten-acre lots are sought to be patented, in addition to the other data required in the notice.

Sixtieth. Where the ten-acre subdivision is in the form of a square, it may be described, for instance, as the "S. E. $\frac{1}{4}$ of the S. W. $\frac{1}{4}$ of N. W. $\frac{1}{4}$," or, if in the form of a parallelogram as aforesaid, it may be described as the "W. $\frac{1}{2}$ of the W. $\frac{1}{2}$ of the S. W. $\frac{1}{4}$ of the N. W. $\frac{1}{4}$ (or the N. $\frac{1}{2}$ of the S. $\frac{1}{4}$ of the N. E. $\frac{1}{4}$ of the S. E. $\frac{1}{4}$) of section —, township —, range —," as the case may be; but, in addition to this description of the land, the notice must give all the other data that is required in a mineral application, by which parties may be put on inquiry as to the premises sought to be patented.

Sixty-first. The proceedings necessary for the adjustment of rights where a known vein or lode is embraced by a placer claim, are so clearly defined in the eleventh section of the act, as to render any particular instructions upon that point at this time unnecessary.

Sixty-second. When an adverse claim is filed to a placer application, the proceedings are the same as in the case of vein or lode claims, already described.

Quantity of Placer Ground Subject to Location.

Sixty-third. By the twelfth section of the said amendatory act of July 9, 1870 (third proviso), it is declared "that no location of a placer claim hereafter made shall exceed one hundred and sixty acres for any one person, or association of persons, which location shall conform to the United States surveys," etc.

Sixty-fourth. The tenth section of the act of May 10, 1872, provides that "all placer mining claims hereafter located shall conform as near as practicable with the United States system of public land surveys, and the rectangular subdivisions of such surveys, and no such locations shall include more than twenty acres for each individual claimant."

Sixty-fifth. The foregoing provisions of law are construed to mean that after the ninth day of July, 1870, no location of a placer claim can be made to exceed one hundred and sixty acres, whatever may be the number of locators associated together, or whatever the local regulations of the district may allow; and that from and after the passage of said act of May 10, 1872, no location made by an individual can exceed twenty acres, and no location made by an association of individuals can exceed one hundred and sixty acres, which location of one hundred and sixty acres cannot be made by a less number than eight bona fide locators, but that whether as much as twenty acres can be located by an individual, or one hundred and sixty acres by an association, depends entirely upon the mining regulations in force in the respective districts at the date of the location; it being held that such mining regulations are in no way enlarged by said acts of Congress, but remain intact and in full force with regard to the size of locations, in so far as they do not permit locations in excess of the limits fixed by Congress, but that where such regulations permit locations in excess of the maximums fixed by Congress as aforesaid, they are restricted accordingly.

Sixty-sixth. The regulations hereinbefore given as to the manner of marking locations on the ground, and placing the same on record, must be observed in the case of placer locations, so far as the same are applicable; the law requiring, however, that where placer claims are upon surveyed public lands, the locations must hereafter be made to conform to legal subdivisions thereof.

Sixty-seventh. With regard to the proofs necessary to establish the possessory right to a placer claim, the said thirteenth section of the act of July 9, 1870, provides that "where said person or association, they and their grantors, shall have held and worked their said claims for a period equal to the time prescribed by the statute of limitations for mining claims for the State or Territory where the same may be situated, evidence of such possession and working of the claims for such period shall be sufficient to establish a right to a patent thereto under this act in the absence of any adverse claim."

Sixty-eighth. This provision of law will greatly lessen the burden of proof, more especially in the case of old claims located many years since, the records of which, in many cases, have been destroyed by fire, or lost in other ways during the lapse of time, but concerning the possessory right to which all controversy or litigation has long been settled.

Sixty-ninth. When an applicant desires to make his proof of possessory right in accordance with this provision of law, you will not require him to produce evidence of location, copies of conveyances, or abstracts of title, as in other cases, but will require him to furnish a duly certified copy of the sworn statement of limitations of mining claims for the State or Territory, together with his sworn statement giving a clear and accurate narration of the facts as to the origin of his title, and likewise as to the continuation of his possession of the mining ground covered by his application; the area thereof, the nature and extent of the mining that has been done thereon; whether there has been any opposition to his possession or litigation with regard to his claim; and if so, when the same ceased; whether such cessation was caused by compromise or by judicial decree, and any additional facts within the claimant's knowledge, having a direct bearing upon his possession and bona fides which he may desire to submit in support of his claim.

Seventieth. There should likewise be filed a certificate under seal of the court having jurisdiction of mining cases within the judicial district embracing the claim, that no suit or action of any character whatever involving the right of possession to any portion of the claim applied for is pending, and that there has been no litigation before said court affecting the title to said claim or any part thereof for a period equal to the time fixed by the statute of limitations for mining claims in the State or Territory as aforesaid, other than that which has been finally decided in favor of the claimant.

Seventy-first. The claimant should support his narrative of facts relative to his possession, occupancy, and improvements by corroborative testimony of any disinterested person or persons

of credibility who may be cognizant of the facts in the case and are capable of testifying understandingly in the premises.

Seventy-second. It will be to the advantage of claimants to make their proofs as full and complete as practicable.

Appointment of Deputy Surveyors of Mineral Claims—Charges for Surveys and Publications—Fees of Registers and Receivers, Etc.

Seventy-third. The twelfth section of the said act of May 10, 1872, provides for the appointment of surveyors of mineral claims, authorizes the Commissioner of the General Land Office to establish the rates to be charged for surveys and for newspaper publications, prescribes the fees allowed to the local officers for receiving and acting upon applications for mining patents and for adverse claims thereto, &c.

Seventy-fourth. The Surveyor-general of the several districts will, in pursuance of said law, appoint in each land district as many competent deputies for the survey of mining claims as may seek such appointment; it being distinctly understood that all expenses of these notices and surveys are to be borne by the mining claimants and not by the United States; the system of making deposits for mineral surveys, as required by previous instructions, being hereby revoked as regards field-work; the claimant having the option of employing any deputy surveyor within such district to do his work in the field.

Seventy-fifth. With regard to the platting of the claim and other office work in the Surveyor-general's office, that officer will make an estimate of the cost thereof; which amount the claimant will deposit with any assistant United States Treasurer, or designated depository in favor of the United States Treasurer, to be passed to the credit of the fund created by "individual depositors for surveys of the public lands," and file with the Surveyor-general duplicate certificates of such deposit, in the usual manner.

Seventy-sixth. The Surveyor-general will endeavor to appoint mineral deputy surveyors, as rapidly as possible, so that one or more may be located in each mining district for the greater convenience of miners.

Seventy-seventh. The usual oaths will be required of these deputies and their assistants as to the correctness of each survey executed by them.

Seventy-eighth. The law requires that each applicant shall file with the Register and Receiver a sworn statement of all charges and fees paid by him for publication of notice and for survey; together with all fees and money paid the Register and Receiver, which sworn statement is required to be transmitted to this office, for the information of the Commissioner.

Seventy-ninth. Should it appear that excessive or exorbitant charges have been made by any surveyor or any publisher, prompt action will be taken with the view of correcting the abuse.

Eightieth. The fees payable to the Register and Receiver, for filing and acting upon applications for mineral land patents, made under said act of May 10, 1872, are five dollars to each officer, to be paid by the applicant for patent at the time of filing, and the like sum of five dollars is payable to each officer by an adverse claimant at the time of filing his adverse claim.

Eighty-first. All fees or charges under this act, or the act of which it is amendatory, may be paid in United States currency.

Eighty-second. The Register and Receiver will, at the close of each month, forward to this office an abstract of mining applications filed, and a register of receipts, accompanied with an abstract of mineral lands sold.

Eighty-third. The fees and purchase money received by Registers and Receivers must be placed to the credit of the United States in the Receiver's monthly and quarterly account, charging up in the disbursing account the sums to which the Register and Receiver may be respectively entitled as fees and commissions, with limitations in regard to the legal maximum.

Eighty-fourth. The thirteenth section of the said act of May 10, 1872, provides that all affidavits required under said act, or the act of which it is amendatory, may be verified before any officer authorized to administer oaths within the land district where the claims may be situated, in which case they will have the same force and effect as if taken before the Register or Receiver, and that in cases of contest as to the mineral or agricultural character of land, the testimony and proofs may be taken before any such officer on personal notice of at least ten days to the opposing party, or if said party cannot be found, then, after publication of notice for at least once a week for thirty days, in a newspaper, to be designated by the Register as published nearest to the location of such land, proof of which notice must be made to the Register.

Eighty-fifth. The instructions heretofore issued with regard to disproving the mineral character of lands are accordingly modified so as to allow proof upon that point to be taken before any officer authorized to administer oaths within the land district, and that where the residence of the parties who claim the land to be mineral is known, such evidence may be taken without publication, ten days after the mineral claimants or affiants shall have been personally notified of the time and place of such hearing; but in cases where such affiants or claimants cannot be served with personal notice, or where the land applied for is returned as mineral upon the township plat, or where the same is now or may hereafter be suspended for non-mineral proof, by order of this office, then the party who claims the right to enter the land as agricultural will be required, at his own expense, to publish a notice once each week for five consecutive weeks in the newspaper of largest circulation published in the county within which said land is situated, or if no newspaper is published within such county, then in a newspaper published in an adjoining county; the newspaper in either case to be designated by the Register; which notice must be clear and specific, embracing the points required in notices under instructions from this office of March 20, 1872, and must name a day after the last day of publication of such notice, upon testimony as to the character of the land will be taken, stating before what magistrate or other officer such hearing will be had, and the place of such hearing.

Mill-Sites.

Eighty-sixth. The fifteenth section of said acts provides, "That where non-mineral land not contiguous to the vein or lode is used or occupied by the proprietor of such vein or lode for mining or milling purposes, such non-adjacent surface ground may be embraced and included in an application for a patent for such vein or lode, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notice, as are applicable under this act to veins or lodges; *Provided*, That no location hereafter made of such non-adjacent land shall exceed five acres, and payment for the same must be made at the same rate as fixed by this act for the superficies of the lode. The owner of a quartz mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill-site as provided in this section."

Eighty-seventh. To avail themselves of this provision of law, parties holding the possessory right to a vein or lode, and to a piece of land not contiguous thereto, for mining or milling purposes, not exceeding the quantity allowed for such purpose by the local rules, regulations, or customs, the proprietors of such vein or lode may file in the proper land office their application for a patent, under oath, in manner already set forth herein, which application, together with the plat and field notes, may include, embrace, and describe in addition to the vein or lode, such non-contiguous mill-site, and after due proceedings as to notice, etc., a patent will be issued conveying the same as one claim.

Eighty-eighth. In making the survey in a case of this kind, the lode claim should be described in the plat and field notes as "Lot No. 37, A," and the mill-site as "Lot No. 37, B," or whatever may be its appropriate numerical designation; the course and distance from a corner of the mill-site to a corner of the lode claim to be invariably given in such plat and field notes, and a copy of the plat and notice of application for patent must be conspicuously posted upon the mill-site as well as upon the vein or lode for the statutory period of sixty days. In making the entry, no separate receipt or certificate need be issued for the mill-site, but the whole area of both lode and mill-site will be embraced in one entry, the price being five dollars for each acre and fractional part of an acre embraced by such lode and mill-site claim.

Eighty-ninth. In case the owner of a quartz mill or reduction works is not the owner or claimant of a vein or lode, the law permits him to make application therefor in the same manner prescribed herein for mining claims, and after due notice and proceedings, in the absence of a valid adverse filing, to enter and receive a patent for his mill-site, at said price per acre.

Ninetieth. In every case there must be satisfactory proof that the land claimed as a mill-site is not mineral in character, which proof may, where the matter is unquestioned, consist of the sworn statement of the claimant, supported by that of one or more disinterested persons, capable from acquaintance with the land to testify understandingly.

Ninety-first. The law expressly limits mill-site locations made from and after its passage to five acres, but whether so much as that can be located, depends upon the local customs, rules, or regulations.

Ninety-second. The Registers and Receivers will preserve an unbroken consecutive series of numbers for all mineral entries.

Proofs of Citizenship of Mining Claimants.

Ninety-third. The proof necessary to establish the citizenship of applicants for mining patents, whether under the present or past enactments, it will be seen by reference to the sev-

enth section of the act under consideration, may consist, in the case of an individual claimant, of his own affidavit of the fact; in the case of an association of persons not incorporated, of the affidavit of their authorized agent, made on his own knowledge or upon information and belief, that the several members of such association are citizens; and in the case of an incorporated company, organized under the laws of the United States, or the laws of any State or Territory of the United States, by the filing of a certified copy of their charter or certificate of incorporation.

Ninety-fourth. These affidavits of citizenship may be taken before the Register or Receiver, or any other officer authorized to administer oaths within the district.

Ninety-fifth. Copies of the previous mining statutes of Congress, dated respectively July 26, 1866, and July 9, 1870, are hereto attached. Sections one, two, three, four and six of the former being expressly repealed by the ninth section of the act of May 10, 1872, aforesaid, which in its sixteenth section also repeals all acts and parts of acts inconsistent with its provisions.

Ninety-sixth. The foregoing will be followed in due time by such further instructions as actual experience in the administration of the statute may render necessary.

Very respectfully,

Your obedient servant,

WILLIS DROMMOND, Commissioner.

To Registers and Receivers and Surveyors-general.

Mining Statute of July 26, 1866.

AN ACT granting the right of way to ditch and canal owners over the public lands, and for other purposes.

[NOTE.—Sections 1, 2, 3, 4 and 6 of this act have been repealed, so they are not given here.—ED.]

SECTION 5. *And be it further enacted*, That as a further condition of sale, in the absence of necessary legislation by Congress, the local Legislature of any State or Territory may provide rules for working mines, involving easements, drainage, or other necessary means to their complete development; and those conditions shall be fully expressed in the patent.

Sec. 7. *And be it further enacted*, That the President of the United States be, and is hereby, authorized to establish additional land districts, and to appoint the necessary officers under existing laws, whenever he may deem the same necessary for the public convenience in executing the provisions of this act.

Sec. 8. *And be it further enacted*, That the right of way for the construction of highways over public lands, not reserved for public uses, is hereby granted.

Sec. 9. *And be it further enacted*, That whenever, by priority of possession, rights to the use of water for mining, agricultural, manufacturing, or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same; and the right of way for the construction of ditches and canals for the purposes aforesaid is hereby acknowledged and confirmed; *Provided*, however, that whenever, after the passage of this act, any person or persons shall, in the construction of any ditch or canal, injure or damage the possession of any settler on the public domain, the party committing such injury or damage shall be liable to the party injured for such injury or damage.

Sec. 10. *And be it further enacted*, That whenever, prior to the passage of this act, upon the lands heretofore designated as mineral lands, which have been excluded from survey and sale, there have been homesteads made by citizens of the United States, or persons who have declared their intention to become citizens, which homesteads have been made, improved, and used for agricultural purposes, and upon which there have been no valuable mines of gold, silver, copper, or other minerals discovered, and which are properly agricultural lands, the said settlers or owners of such homesteads shall have a right of pre-emption thereto, and shall be entitled to purchase the same at the price of one dollar and twenty-five cents per acre, and in quantity not to exceed one hundred and sixty acres; or said parties may avail themselves of the provisions of the Act of Congress, approved May twenty, eighteen hundred and sixty-two, entitled "An act to secure homesteads to actual settlers on the public domain," and acts amendatory thereof.

Sec. 11. *And be it further enacted*, That upon the survey of the lands aforesaid, the Secretary of the Interior may designate and set apart such portions of the said lands as are clearly agricultural lands, which lands shall thereafter be subject to pre-emption and sale as other public lands of the United States, and subject to all the laws and regulations applicable to the same. Approved, July 26, 1866.

Mining Statute of July 9, 1870.

AN ACT to amend "An Act granting the right of way to ditch and canal owners over the public lands, and for other purposes."

[NOTE.—All that part of the law from section one to eleven inclusive has been repealed, and is not given here.—ED.]

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the act granting the right of way to ditch and canal owners over the public lands, and for other purposes, approved July twenty-six, eighteen hundred and sixty-six, be, and the same is hereby amended, by adding thereto the following additional sections, numbered twelve, thirteen, fourteen, fifteen, sixteen, and seventeen, respectively, which shall hereafter constitute and form a part of the aforesaid act.

Sec. 12. *And be it further enacted*, That claims usually called "placers," including all forms of deposit, excepting veins of quartz, or other rock in place, shall be subject to entry and patent under this act, under like circumstances and conditions, and upon similar proceedings, as are provided for vein or lode claims; *Provided*, that where the lands have been previously surveyed by the United States, the entry, in its exterior limits, shall conform to the legal subdivisions of the public lands, no further survey or plot in such case being required, and the lands may be paid for at the rate of two dollars and fifty cents per acre; *Provided*, further, that legal subdivisions of forty acres may be subdivided into ten-acre tracts; and that two or more persons, or associations of persons, having contiguous claims of any size, although such claims may be less than ten acres each, may make joint entry thereof; *And, provided further*, that no location of a placer claim, hereafter made, shall exceed one hundred and sixty acres for any one person or association of persons, which location shall conform to the United States surveys; and nothing in this section contained shall defeat or impair any bona fide pre-emption or homestead claim upon agricultural lands, or authorize the sale of the improvements of any bona fide settler to any purchaser.

Sec. 13. *And be it further enacted*, That where said person or association, they and their grantors, shall have held and worked their said claims for a period equal to the time prescribed by the statute of limitations for mining claims of the State or Territory where the same may be situated, evidence of such possession and working of the claims for such period shall be sufficient to establish a right to a patent thereto under this act, in the absence of any adverse claim; *Provided*, however, that nothing in this act shall be deemed to impair any lien which may have attached in any way whatever to any mining claim or property thereto attached prior to the issuance of a patent.

Sec. 14. *And be it further enacted*, That all ex parte affidavits required to be made under this act, or the act of which it is amendatory, may be verified before any officer authorized to administer oaths within the land district where the claims may be situated.

Sec. 15. *And be it further enacted*, That Registers and Receivers shall receive the same fees for services under this act as are provided by law for like services under other acts of Congress; and that effect shall be given to the foregoing act according to such regulations as may be prescribed by the Commissioner of the General Land Office.

Sec. 16. *And be it further enacted*, That so much of the act of March third, eighteen hundred and fifty-three, entitled "An Act to provide for the survey of the public lands of California, the granting of pre-emption rights, and for other purposes," as provides that none other than township lines shall be surveyed where the lands are mineral, is hereby repealed. And the public surveys are hereby extended over all such lands; *Provided*, that all subdividing of the surveyed lands into lots of less than one hundred and sixty acres may be done by county and local surveyors at the expense of the claimants; *And, provided further*, that nothing herein contained shall require the survey of waste or useless land.

Sec. 17. *And be it further enacted*, That none of the rights conferred by sections five, eight, and nine of the act of which this is amendatory shall be abrogated by this act; and the same are hereby extended to all public lands affected by this act; and all patents granted, or pre-emption or homesteads allowed, shall be subject to any vested and accrued water rights, or rights to ditches and reservoirs used in connection with such water rights as may have been acquired under or recognized by the ninth section of the act of which this act is amendatory. But nothing in this act shall be construed to repeal, impair, or in any way affect the provisions of the "Act granting to A. S. the right of way and other privileges to aid in the construction of a draining and exploring tunnel to the Comstock lode, in the State of Nevada," approved July twenty-fifth, eighteen hundred and sixty-six. Approved July 9, 1870.

DURYEA'S SATIN GLOSS STARCH AND DURYEA'S IMPROVED CORN STARCH

Are the Best in the World.

USE IT ONCE AND YOU WILL USE NO OTHER.

For Sale by All Grocers.

FAC-SIMILES OF PRIZE MEDALS AWARDED THE

The Messrs. Duryea have succeeded in refining Starch to entire purity and developing its entire strength and clearness, an improvement that will be readily perceived in the greater strength of the Starch & the superior luster that it gives, and in its reliable uniformity. Much of the so-called starch contains from one-fourth to one-third for impurities, readily perceived by sourness, mudiness, or a golden yellow tinge, peculiar to inferior starches, a color not desirable for one's linen, but inseparable from the use of common starch. They pledge themselves to the public to give uniformly superior article, from one-fourth to one-third stronger than any other starch in the world, and at the common market rates.

DUNBAR'S WONDERFUL DISCOVERY.

BETHESDA MINERAL SPRING WATER Of Waukesha, Wisconsin.

We claim Bethesda to be a specific in all cases of Diabetic Inflammation of the Kidneys, Inflammation of the Neck of the Bladder and Urethra, Inflammation of the Bladder, Dropsy, Gouty Swellings, Stoppage of Urine, Albuminuria, Ropy or Cloudy Urine, Brick Dust Deposit, Thick, Morbid, Bilious and Dark Appearing Urine, with Bone Dust Deposits, Burning Sensation with Sharp Pains when voiding Urine; Hemorrhage of the Kidneys, Pain in the Kidneys and Loins, Torpid Liver Indigestion, Calculus, and Female Weakness.

There is no remedial agent known to man that can cure the foregoing diseases as effectually as Bethesda Water. This fact has been demonstrated wherever the water has been used according to directions, which can be had at the General Agents' by application to them. The water is sweet and pleasant to the taste. It can be drunk at all hours. Why should any one suffer while this Water is so easily obtained?

KNOWLES' PATENT STEAM PUMP.

It has no Cranks or Fly-Wheel, and has no dead points where it will stop, consequently it is always ready to start without using a starting-bar, and does not require hand-work to get it past the center. Will always start when the steam cylinder is filled with cold water of condensation.

CENTRAL PACIFIC R. R. OFFICE OF THE GEN'L MASTER MECHANIC, SACRAMENTO CAL., January 14, 1875.

A. L. FISH, Esq., Agent of the Knowles Steam Pump—Dear Sir: In reply to your inquiry as to the merits of the Knowles Steam Pump, in use upon this road, I will say that it gives me great pleasure to report that they have performed their work well whenever called upon. In no instance have they failed. We have now over 30 of them in use on this road as fire engines, and pumping water for shop and station use. I consider the Knowles Steam Pump the best in use, and prefer it to any other.

Yours, truly,

A. J. STEVENS, General Master Mechanic.

A. L. FISH, Agent Knowles' Steam Pump—Dear Sir: In answer to your inquiries, we state that the highest award for Steam Pumps at the Eighth or 1st Mechanics' Fair in San Francisco, was a First Premium and Diploma, awarded to Knowles' Patent Steam Pump, as published in the Official List September 23d, 1871.

KNOX & OSBORN.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

1v29-3m

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Eighth Lecture Delivered before the University of California College of Agriculture, on Thursday, January 28th, by PROF. C. E. BRADY.

Spurgeworts, Laurets and Olives.

The topic to-day is, first, the Spurgeworts, the plants belonging to the order *Euphorbiaceae*. The order is to some extent represented here, so that probably you are somewhat familiar with its characteristics. It is one of the most extensive orders we have, numbering fully three thousand species, distributed in all climates. In the temperate countries they are herbaceous, in many cases very small plants growing to a height of four or five inches. In South and East Africa they have leafless, succulent stems, often rising to the height of trees, being very much in shape like the cactus, while in tropical and South America they become very large trees. Throughout the whole order there is a continuous milkiness in the juice. This juice is in many cases exceedingly poisonous, so that we may put down the order as a poisonous one. The plant of greatest importance is the one from which we derive our supply of India rubber or caoutchouc. It is a large tree, *Siphonia elastica*, growing to a height of eighty or one hundred feet; found in Brazil, Guiana and Central America. It abounds very largely in the islands found in the Amazon river. You know the Amazon river spreads out so that a wide portion of its islands and banks are at times covered with water. In obtaining the rubber, the natives begin just after the water has subsided. They cut into the tree, making great incisions into the sides of the stems, and from these there flows abundance of milky sap. This is collected in large vessels and dried. The usual method is to collect it on some large surface and dry it. The natives found it useful in making all sorts of articles, and so they would make moulds for that purpose. Suppose they wanted to make a bottle; they would make a mould representing the inside of the bottle; they would then dip this mould in the liquid material at intervals, thus forming layer after layer, until the desired thickness is obtained; they would then break the mould and shake it out. Shoes were made in the same way. Even now, the rubber is brought to America very largely in shape of such things. Its black color is largely due to hanging in the smoke. If it was carefully prepared, it would be

Much Lighter Colored.

It is brought here to the United States, also to Great Britain, and manufactured in various forms. The first knowledge Europeans had of it was obtained at the time Columbus first discovered the continent. He found the natives used rubber balls, and various utensils of different kinds; but, until 1820, they made very little use of it but for erasing; from that time it got the name of India rubber. Priestly made the observation that it was useful. In 1820, India rubber clothing was manufactured from it. In 1842, it was hardened by vulcanizing it. Since that, all sorts of uses have been found for it, indeed there is scarcely an industry, scarcely an art, but that has very much to do with this vulcanized rubber. In your chemical works, you find it impossible to get on a day without this, in its vulcanized form. The fear is, it will

Become Extinct.

These natives go in there and cut and slash away at the trees; they take no pains to grow them, so that there is very great danger of their being entirely destroyed. Probably the best way to remedy this is to call the attention of governments to the subject. Great Britain has been memorialized. Our Government ought to be also. It could be grown on any of the islands lying within the tropics.

The box tree, *Buxus sempervirens*, is a native of Europe and also of Asia. It grows to the height of twenty to thirty feet, and attains a diameter of four, six, eight or ten inches. It very seldom grows larger than this. Its use is for manufacturing the finer mathematical instruments, and also bushing and works of the smaller kinds of machinery, also in engraving, because of the hardness and fineness of its wood. In engraving it is very much used, as it is fitted especially for this. Our supply comes almost entirely from the Mediterranean basin and from the region lying in the vicinity of the Black sea.

It Can Be Grown Here

Very readily, can be grown throughout almost all parts of the Southern United States. Its growth is slow; however, it should be introduced here. It is the same thing as the English box.

English box is only the dwarf variety, and as this grows very readily—being cultivated as a border plant—it is probable that the tree would do well here. In fact, our climate is very much like the climate in which the tree grows. The castor oil plant, *ricinus communis*. A large, herbaceous plant, native of the East Indies, now grown in almost all of the warmer climates; grown as far north as 38° to 40° in the United States; is grown now in portions of Missouri and also in portions of Illinois, and States being southward. From its seed castor oil used largely in medicine) is obtained by

pressure. In Central Europe it is grown for feeding silk-worms. The leaves are very large and there are a great many on each plant, so that a great deal of food is provided in this way for the worms.

There are a great many other plants belonging to this order which are of a good deal of importance, but I have selected some of the most value. I might have mentioned the *croton tiglium* of India, from which croton oil is obtained.

African teak is the product of *Oldfieldia Africana*, and is a very heavy, hard wood. It is found that it is best to use in constructing steamships, in building up the woodwork near the fires and near the boilers. It seems to stand a

High Degree of Heat

Without catching fire. Ought to be more largely used. It, however, comes from Africa, so that we probably cannot grow it here.

The laurel group, *Lauraceae*, is not a large family, numbering only about five hundred species. These are mostly evergreen trees, and are found in the temperate and tropical climates. Throughout the whole order there runs a sort of aromatic principle which in some cases is sufficiently concentrated to become medicinally valuable.

The order derives its name from the bay tree, or the laurel tree, as it is sometimes called; *Laurus nobilis*, a native of Europe. This is the bay, or the laurel that we read so much about in literature. It is a tree about forty or fifty feet in height, and has beautiful leaves, to some extent resembling the leaves of trees here. In olden times these leaves were used to crown heroes—now-a-days they are put to other uses. The testimony runs this way: They are used for flavoring custards and puddings, and for imparting a

Fictitious Flavor to Figs

When packed for shipping. Bay rum is not from that tree, but from one allied to it.

Cinnamon, *Cinnamomum Zeylanicum*, is a native evergreen tree of Ceylon, and is extensively cultivated on that island, also on the Malabar coast, and in Java and Cayenne, for the sake of the aromatic bark of its young branches.

It is a shrub tree; that is, it is very much inclined to send up a great many reed-like little stems, and they are selected for peeling when they are about three years old, and one-half inch to an inch in size. Workmen go along, run their knives down the sides of these stems, and the whole bark is stripped off. In a day or two the epidermis—corky and green layers—can be removed, so that only the older inner fibers of the bark remain. This takes on a brown color, and is brought to market in the quill-like form in which it is arranged. In selecting, the outer bark is rejected in the true cinnamon. True cinnamon should be of a rich brown color; should be very thin, about as thick as four or five sheets of paper, not much thicker than that, and should be exceedingly fragrant.

Now, allied to this tree from which true cinnamon is obtained, we have two others—C.

Fig. 1. The Olive Branch.

aromaticum and *C. cassia*, natives of Ceylon, from which, as well as from the older branches of the species already noticed, cassia bark—may be considered as a kind of inferior cinnamon—is obtained. This bark is thicker and has more of a bitterness and a pungency than the true cinnamon. Instead of occurring in long, quill-like pieces, it is in the form of thick chips; as, instead of taking that great pains which they do with true cinnamon, they simply cut and slash away at it in about the same way we would take a drawing-knife and peel off the bark of an ordinary tree. It is used as a substitute for, and also to mix with, the true cinnamon. You go to any of the ordinary shops and call for cinnamon, you will find what is properly called *cassia bark* in it and some places it is found without any cinnamon at all. I have seen many specimens that seemed to be

Nothing but Cassia Bark.

Whenever you find cinnamon occurring in chip-like masses you may be sure it is not true cinnamon at all, but it is really cassia bark. Taking the British statistics, the amount annually consumed in England is some thirty to forty tons true cinnamon and about two hundred tons of this cassia bark which might be called false cinnamon. Cassia buds are derived from the last named species.

The camphor tree, *Camphora officinarum*, be-

longs to this order; is a native of China and Japan and is now grown very much on the island of Formosa. The wood is of considerable value. It is used in the manufacture of trunks, chests and other things where the fragrance is of some importance, and from the wood is also obtained the camphor that is found in the shops.

In order to obtain this, the wood is chopped up, thrown into water and subjected to heat; camphor being volatile, passes over and is condensed. It is then brought to this country and used for medicine. Clothes put into a trunk or chest made of camphor-wood, are almost always preserved from moths, as these insects seem not to like it.

The California laurel, *Oreodaphne Californica*, is our only representative of this order. It is possible, another representative one—a little shrubby one—may be found here. But this, I understand, the only one giving value to the order here. The wood of this laurel is, as you know,

Quite Valuable.

I find that it has not been used as much as it might have been, or as much as it should be. It is considered sufficiently ornamental in England to be used in the gardens there quite considerably, and there they have introduced it

Broadbros' Excelsior Pruning Shears.

under a different name, and I have little doubt but that you will find it before many years brought back from there and sold under that name to our people for a new plant. Of course it will do very well. It will do just as well to use the wild plant, however.

In the United States, east of the Rocky mountains, another tree, the *Sassafras*, (*Sassafras officinalis*), is of some importance, as furnishing a very spicy bark which is supposed to be very valuable in medicine; it is used somewhat.

The last family that I call your attention to, is the

Olive Family.

Oleaceae, (see fig. 1). It is smaller than the preceding, numbering but a hundred and fifty species. They are all trees; or, if they are not trees, they are shrubs. We might say they are trees, or shrubs more or less inclined to be tree-like, natives of the temperate, northern hemisphere, and to a limited extent of the southern. The order is of importance, as furnishing us some valuable woods. First or probably most important is the European ash, (*Fraxinus Excelsior*), a large tree extensively planted in Europe. The wood is used wherever strength, lightness and hardness are desirable. Without any question this could be very profitably introduced into California. It would grow without any doubt, and as we are somewhat short of wood of that character, it would be well to see what could be done by way of introducing it. In the eastern United States, *Fraxinus Americana* seems to take its place. It is there called white ash, and is somewhat related to the European one. Its wood is equally valuable, and it is largely used for the insides of railroad and street cars. For any use where lightness and toughness are necessary, it is valuable. It is used very largely in the manufacture of useful agricultural implements, and when kept reasonably dry the wood is very durable also. This American species grows somewhat larger than the *Excelsior*, preferring the rich soils lying midway between the lowlands and uplands, and

Might be Introduced Here with Advantage. But probably it could not be as well grown as the European, so I would advise the introduction of the *Excelsior* rather than the *Americana*. In some parts of California occurs what is called Oregon ash, (*F. Oregona*). It is a tree attaining a diameter of from twelve inches upwards, found in Oregon and probably the northern portions of this State. I don't know whether it grows as far south as this or not.

I have here specimens from a small tree of it, also the curly form which seems to have been taken from a knot or something like that. I could not find any of the straight-grained timber in the collection. This is very largely used here in the city of San Francisco. I find that our manufacturers use it very extensively. They use it along with the *Americana* which they import from the Eastern States.

The name of the order is derived from the olive, *Olea Europea*. It is a native probably of

Western Asia. Its name would lead one to suppose it was a native of Europe, but that is not the case. It is, I think, grown to a limited extent in the southern portion of this State, somewhat in the Southern U. S., in the West India Islands, but more extensively in the basin of the Mediterranean. From its fruit, which is a small, blue black, cherry-like fruit, is obtained the sweet olive oil. This fruit is gathered ripe, subjected to pressure for the purpose of extracting the oil. The wood of the tree is very hard, of a yellowish white color and is exceedingly durable. It is used in the manufacture of small implements and utensils in very nearly the same way that box-wood is used and can be used for very nearly the same purposes.

Manna, found in the shops, is the product of a species of ash, *Fraxinus arnus*, found in Southern Europe. Calling for manna at any of the druggists, you will be shown a very peculiar, waxy material which is the product of *Fraxinus arnus*. Upon making incisions into the tree the juice exudes and hardens, producing manna.

The order is of some little importance for its ornamental representatives. Of these we need only mention the fringe tree, grown extensively in Quebec; the lilac and the jessamine. Having gone over three groups, although I have not used up the hour by any means, I perhaps have given you material enough to work up for this time.

Broadbros' Excelsior Pruning Shears.

We illustrate herewith a novel pruning shears, the feature of which is a cam-shaped blade, for giving a very powerful drawing cut.

Fig. 1 represents the shears partially open, showing how the drawing cut is secured. Fig. 2 is the wrench or lever, provided with a hook and stud that drop in perforations on the blade, Fig. 4. Fig. 3 is the other handle, with the blade turned back against the shank, forming, when used singly or without the lever wrench, a hatchet, or knife, for trimming small limbs, sprouts or shrubbery. The cam-shaped knife-blade is provided with a series of perforations to receive the hook and stud of the lever wrench. When the handles, Fig. 1, are brought toward each other, as is evident, the drawing cut is produced. The point of contact of the knife edge with the limb, where the power is to be applied to do the cutting, is inside the pivot or bolt that holds the blade. The shape of the hook, Fig. 3, is such as to bring the limb to be cut directly under the fulcrum or pivot on which the blade operates. When the knife blade is applied it holds the limb firmly until cut, and prevents its slipping on the hook. Injury to the bark is prevented, also any crushing of the limbs, the ends being left smooth enough for grafting. In other pruning shears, where the power is applied outside of, and at a distance from the fulcrum or pivot which holds the two jaws together, slipping of the limb often occurs, thereby mangling the bark. The very long handles also employed frequently crush the branches. The handles of the shears represented in the engraving are only eighteen inches in length, so that the power is in the shears itself instead of in long handles.

The efficiency of the device is very remarkable, judging from specimens of its operation forwarded to us. Two fragments of boughs are before us—one 1½ inches, and the other 2½ inches in diameter, each of which has been divided with a clean, smooth cut, apparently at a single stroke. The wood is hard maple and the length of the cut is greater than the above diameters, owing to its being made at an angle.

For information relative to the additional advantages of the tool, and descriptive circulars, address Broadbros & Co., Batavia, N. Y.

Interesting Analogies in Nature.

A physician has recently published a pamphlet advancing a curious theory of the "oneness of the earth system." This he attempts to prove by means of the resemblance in form between the parts of the human body and many vegetable productions; and the following are some of the analogies in his ingenious argument:

"Thus the cocoa-nut is, in many respects, like the human skull, although it more closely resembles the skull of the monkey, and may perhaps serve Darwin's purpose as a link between the two; a sponge may be so held as to remind one of the unfinished face of the skeleton; and the meat of an English walnut is almost an exact representation of the brain. Plums and black cherries resemble the human eye; almonds and some other nuts resemble the different varieties of the human nose; and an open oyster and its shell are a perfect image of the human ear. 'The shape of almost any man's body,' we are told, 'may be found in the various kinds of mammoth pumpkins.' The open hand may be found in the form assumed by scrub willows and growing celery. The German turnip and the egg plant resemble the human heart. The author finds other striking resemblances between human organs and certain vegetable forms. In the course of his investigations he traces the forms of many mechanical contrivances now in common use back to the patterns furnished by nature. Thus he tells us that the hog suggested the plow, the butterfly the ordinary hinge, the toadstool the umbrella, the duck the ship, the fungus growth on trees the bracket."

Pliocene Terraces in California.

[By J. O. Cooper, M.D.]

The recent article by Mr. Amos Bowman, on "Terraces in the Coast Range" (MINING AND SCIENTIFIC PRESS, March 20, 1875), disputes some of the facts stated by me in an article on "California in the Pliocene Epoch," printed in your journal for Oct. 10th, 1874. I am therefore called upon to notice briefly a few of the points in which Mr. Bowman's statements differ from my own.

1. I am willing to leave it to the observation of any impartial geologist whether any terraces can be seen on the San Francisco peninsula north of Point Pedro or inside the Golden Gate, either east or west of the Bay.

2. The terraces described by Prof. Davidson cannot be traced by anyone (except Mr. Bowman), north of Point Pedro or inside of the Bay. Where they do exist abundantly, as near Santa Cruz, they are evidently post-pliocene, for they have been cut from the slopes of pliocene and miocene strata, which themselves are usually inclined at angles quite uncomfortable with the terraces.

3. If any one sees evidence in my paper that I consider "terrace as signifying the same thing as a bed or stratum," I hope the above statement will correct the idea. In certain cases, however, terraces do conform to strata of undoubtedly pliocene age, and these I referred to as existing "at low levels around the Bay." These are not, however, marine terraces, but of fresh water origin, and have not been described in any printed work. When the state of California becomes rich enough to publish the results of several years' work done by one of her most faithful and unjustly abused scientists, the late State Geologist, and his assistants, something more will be known of these interesting formations. Meantime, it is better to "go slow," and state only well determined facts.

4. If Mr. Bowman found any Pliocene shells at heights of 700 and 1000 feet (as he may have done), they must have been washed from the highly inclined marine pliocene strata between Lake Merced and Point Pedro. As the terraces were the effect of erosion "by the receding sea," of course no deposits of shells could be found in them. I am happy to say that I agree with Mr. Bowman as well as with all geologists that I know of, in considering the marine terraces outside of the bay as thus formed, and that there is no evidence to sustain Prof. Davidson's theory that ice assisted in this action. Similar erosion is still going on, especially on the southern coast. This is so generally accepted that I did not consider it worth discussion in former articles.

5. I did not attempt to connect these Coast Range uplifts with the Pliocene strata of the Sierra Nevada, having seen but little of the latter, and I consider the evidence so far known to prove a long period of time between the older and newer of the pliocene formations, but do not propose now to discuss this point further than to state that similar fresh water deposits were made in the Coast Range at a rather later time than those so extensive in the Sierra.

6. The last column of Mr. Bowman's article is rather obscure, but if he wishes for evidence of volcanic outflows above glacial moraines and striated rocks, I doubt not he can find it near the recent volcano described by Dr. Harkness in the MINING AND SCIENTIFIC PRESS of November 21st, 1874, as well as about many others less recent. He may find, by late geological text-books, that since the pliocene epoch there have been vast changes in the earth's surface, before any evidence is found of man's existence; changes as great as the new river beds of the Sierra seem to require. Using the term quaternary instead of post pliocene, Prof. Dana divides it thus:

Quaternary Age.

Period 1. Glacial or drift. Period 2. Champlain (melting). Epoch 1. Diluvian. Epoch 2. Alluvial. Epoch 3. Recent. Era 1. Reindeer or second glacial. Era 2. Modern.

In Europe, if not in America, man probably existed in the reindeer era. The *Mastodon Americanus* seems to have been cotemporary, even if the last of this species was not killed by man, as has been asserted. Now, the most complete estimate (Dana's Manual, 1874, p. 590), gives between 31,000 and 380,000 years as having elapsed since the mastodon existed in the later Champlain epochs, just before the recent period began. Taking the lowest estimate as right, there has certainly been ample time for all of our surface erosions.

DURING the year 1874 the coinage executed at the Carson mint in gold was 158,139 pieces, worth \$2,670,675, and in silver 1,459,017 pieces, worth \$1,411,781 70. The average during 1874 was three times greater than any previous year. The coinage at present consists of \$300,000 in gold and \$200,000 in silver per month. The monthly deposits amount to \$400,000 in gold and \$300,000 in silver.

THE water has been drained from shaft No. 2 on the line of the Sutro tunnel. There is still a considerable flow through the drill-hole made from the header, but it is only of water which naturally flows from the west country rock.

ABOUT 600 men are now at work in the Consolidated Virginia mine. In all, the company employ nearly 800 men.

Brooks' Improvement in Distilling.

A correspondent writes us from Santa Clara as follows: "In a late number of your journal you give a partial description of an alleged improvement in distilling, patented by Mr. Brooks, at the close of which you promise to speak again of the invention. In case you do, will you please enlighten us on a point mentioned, which I cannot understand? While Mr. Brooks' arrangement may work satisfactory in practice, the theory must be wrong, in my view. We all know that water, unless confined in a steamtight vessel, can not be raised to a higher degree than 212°. Now, water being somewhat thicker, may be raised a few degrees higher, but never to 269°, which is said to be necessary to vaporize fusil. But we all know that fusil will pass over, consequently it must vaporize at little above the boiling point of water, or it would not do it, and would remain in the wort. Will you please explain?"

In answer to the above, we inform our correspondent that Mr. Brooks does not vaporize the fusil oil, but leaves it in the wort. His still is so constructed that he cannot by any possibility create a pressure inside of it, therefore, the heat in the still being not over 212°, the fusil oil which requires 269° of heat to be converted into vapor must of necessity remain in the wort, and when the spent wort is withdrawn from the still, the fusil oil goes with it to the sewer. The ether is first got rid of by a preliminary condensing process, and is entirely withdrawn from the still before the alcoholic vapors begin to vaporize. This leaves him free to withdraw the alcohol, water and essential oil of the grain without fear of carrying over the fusil.

The Microscopical Society.

The San Francisco Microscopical Society held its regular meeting on Thursday evening, President Ashburne in the chair. Two proposals for resident membership were received, and Henry Molineaux, Esq., was elected as such.

Under the head of donations to the cabinet, Mr. C. G. Ewing presented a slide mounted with a colony of polyps, *serularia*, in glycerine from San Pedro bay.

C. Mason Kinne donated five slides mounted by him, comprising the elytron of a beetle, showing very marked peculiarities; raw cotton from near Visalia, Cal.; scale of salmon; raw cotton from New Mexico; and white horse hair; the three last named being mounted in balsam, for the polariscope, and which proved worthy objects for observation with that accessory. Col. Kinne exhibited some living *protococcus*, which vegetable, moving freely in the same drop of water with the animal forms *paramacium vorticella* and others, and aided to show how nearly the two great animal kingdoms are allied in the so-called lower forms of life.

Dr. Eiseu exhibited the tentacles of barnacles (*lepas*), and a variety of marine algae (*ulva*).

Mr. Hyde, Vice-President of the Society, read an interesting letter addressed to the members of the Society, from Mr. Joseph Beck of London, corresponding member, from which we quote the following: "It is from those enthusiastic and ardent workers with our favorite instrument, living in new countries and surrounded with objects inviting their examination, that we expect fresh contributions to our stock of knowledge. In microscopical apparatus there is but little new. We have increased the angle of our Achromatic Condenser to suit the purposes of those who are still studying the ultimate structure of the diatoms, and under the direction and with the assistance of Mr. Sorby, are introducing various novelties in connection with the spectroscopic, which is still claiming much attention. The intricate nature of some of these investigations, and the uncertainties attending some of them, have led some even to doubt the value of results obtained; but each new fact is a step in advance, and I cannot but believe that in due time the appearance presented under this instrument will be of great value to science. We have yet much to learn, and I think that one branch that may be of use will be the ascertaining of the time required for the absorption by vegetables of certain substances, thus aiding both the farmer and the fruit-grower in the cultivation of their crops. Some of the most interesting lectures we have had over here, have been on the instincts and queer reasoning faculties of insects, by Sir J. Lubbock, and on the great discoveries of submarine matter, resulting from the expedition of the "Challenger."

A BLOCK of marble 30 feet 5 inches long, by 20 feet wide, and 10 feet in thickness, weighing about 610 tons, was recently quarried near Columbia, Tuolumne county. It will be reduced to smaller blocks and taken to San Francisco for the Palace Hotel.

SEVERAL mining companies in Nevada county are employing Chinese labor, to the exclusion of white laborers, whereat the latter are very much excited, as it is natural they should be.

WORK has been resumed at the Santa Cruz powder mills, after a stoppage of some weeks. They will run 13 mills, employing 120 hands.

California Railroad Items.

Railroad building and surveying is pretty brisk in California just at present, and a number of new lines are projected. In other places railroads are being extended, and general activity in this line prevails. We append a brief synopsis of what is being done in different places:

A NARROW gauge railroad from San Luis Obispo down the coast to Gualdape in Santa Barbara county, is to be constructed immediately. In fact, two of them, that of Goodall, Nelson & Perkins, and another by the Hartford railroad company; and the Santa Barbara Press urges citizens of that place to build on from there to meet it. If this were done, the road would soon be carried on to Salinas, and railway connections with this city would be soon accomplished. The Goodall & Nelson managers have already purchased nine miles of iron for this road. They have also ordered work to be pushed forward with all possible haste, and the laborers are now on the way. With no obstacles, such as injunctions, this road will be completed in perhaps ninety days. The Hartford company assert their determination to construct their road as originally projected. They claim to have means to construct their proposed road, and will carry out their original plans, regardless of the Goodall & Nelson company. The outlook at present is that they will soon have two roads to San Luis Obispo, and unless the Hartford company make it the terminus of their road, will have two roads south to the Santa Maria valley, which is fast rivaling the Salinas valley as a grain-producing district.

In urging the building of a railroad between Obico and Colusa, the Colusa Sun says, as an inducement, that if the Chicoites will build the road, which will be between thirty-five and thirty-six miles, responsible parties will contract and give bonds in the sum of \$200,000 for the performance of it, to carry freight from Colusa to the side of the ship anywhere in the Bay of San Francisco for \$2 a ton. A survey of the line was commenced on the 17th inst. The surveying party returned on the 22d inst., and report a natural grade without the necessity of a bridge or filling, on the air line road from Colusa to Chico. The distance is thirty-five miles, being over a level, rich, agricultural country. There is no doubt that the road will be built soon enough to carry the fall crop. Colusa and Chico men say the stock will be taken by local capitalists without trouble. The farmers and owners of land along the proposed route are enthusiastic in support of the road, and will take stock to the extent of their means.

The San Lorenzo Flume and the Santa Cruz and Felton railroad company have about 200 men at work, and the work progresses rapidly. The flume will be fourteen miles in length, and about one and three-quarter miles is completed and working with perfect satisfaction. The company's mill is located twenty-one miles from Santa Cruz and cost \$12,000. The railroad will be seven miles long, and most of the surveyed route is graded.

The Mendocino Star learns that a joint stock company has been formed, with a capital of \$30,000, for the purpose of constructing a railroad from the mouth of Salmon creek to its headwaters, known as the Salmon Creek Basin, for the purpose of freighting short lumber to a shipping point on the coast, and perhaps for the purpose of freighting lumber, as it is intimated that a sawmill will probably be built at the headwaters of the creek.

The lease of the San Rafael and San Quentin railroad to the North Pacific Coast company, has been formerly completed, and the new arrangements thereunder were fully inaugurated last week. Three trips are run daily on the same hours as before, but the fare is reduced to 50 cents. The company will at once reduce the gauge of the old road to a narrow gauge.

WORK on the railroad bridge, over Salinas river, which was partially swept away by the flood some time ago, is progressing as rapidly as possible, and the road is expected to be in running order again some time this month.

THE Narrow-Gauge railroad between Salinas City and Monterey, will again soon be in running order, but the exact time cannot yet be stated.

THERE are 300 men at work on the Los Angeles and Independence railroad.

PANAMINT.—A gentleman just in from Panamint gives some items in relation to those mines. The Wyoming ledge is found to be six feet wide at a depth of 144 feet below the surface. The Hemlock and Alabama claims are prospecting equally well with the Wyoming. The company's mill will be ready to go to work in sixty days. All the machinery is now either in Panamint or on wheels on the way for that place.

GOON, efficient mill hands are very scarce now on Puget Sound, W. T., the industrious, the able young men seeming to have mostly left the country—gone north to the mines or south to California. To obviate the difficulties experienced from this cause, the Port Gamble company sent to Machias, Maine, for twenty-five men to come West and work for them.

A GYPSUM mine was discovered a few days since, near Lone City, Amador county. The mine will be immediately opened, if found practicable.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C., March 23, 1875.

FOR WEEK ENDING MARCH 9, 1875.

BILL FILE.—F. B. Alderson, San Jose, Cal.
BUTTON-HOLE CASINO.—Virginia V. Balmfontb. Oakland, Cal.
ROAD SCRAPER.—Abijah McCosh, of Saratoga and James T. Watkins and Jasper M. Scott, Santa Clara, Cal.
NON-FREEZING HYDRANT FOR FIREPLACES ETC.—Huston I. Chapman, Portland, Oregon.
GRAIN AND STRAW LIFTER.—Donald Crane, Knight's Landing, Cal.
WATER ELEVATOR OR CHAIN PUMP.—Orson A. Davis, Washington, Cal.
REVERSIBLE PINION FOR WATCHES.—J. Gordon, San Francisco, Cal.
FRUIT DRYER.—Levi A. Gould, Santa Clara, Cal.
ICE-MAKING APPARATUS.—William Hood, San Francisco, Cal.
ORE FEEDER.—James Tullock, Sonoma, Cal.
EARTH AUGER.—Elijah Whitney, Marysville, Cal.
STUN FASTENING.—Salé Zacharias, S. F. Cal.
METALLURGIC FURNACE.—John Feix, S. F., Cal.
CLOTHES SPARKLER.—William Olson, Sacramento, Cal.

TRADE MARK

For axes.—Richard Patrick & Co., S. F. Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Agricultural Items.

THE rain showers which visited San Francisco on Monday the 22d, though slight, seem to have been quite general in the central and northern part of the State. The following brief weather items of that day will prove of interest: Emigrant Gap.—It is raining a little; thermometer, 44; Blue Cañon.—Calm and raining; thermometer, 42; Rooklin.—Cloudy and windy; Truckee.—Cloudy and snowing the least bit; it is more rain than snow; strong wind from southeast, very cold; Colfax.—Cloudy, wind west; Summit.—Cloudy and calm; thermometer, 28; barometer, 23; it has quit snowing; Marysville.—Cloudy; has been sprinkling this morning; wind south; Chico.—Cloudy; south wind; no rain; cold; Redding.—Raining; Cisco.—Weather drizzling; wind southwest; thermometer, 40; Sacramento.—Cloudy; strong south wind; Shasta.—It commenced to rain here about eight o'clock this evening; wind south; there are prospects of a glorious rain; Tehama.—There are good prospects for rain soon; it is very cloudy; wind southeast; Dixon.—There was a slight sprinkle of rain this morning; weather cloudy and cold; wind south.

NEWMARK & Co. have sold the Santa Anita ranch to Thomas B. Fawcett of San Francisco, for \$200,000 cash. The ranch contains 8,000 acres and is situated in the valley of the San Gabriel river, eleven miles from Los Angeles, and was purchased by Messrs. Newmark & Co. three years since, for \$85,000.

EXPERIMENTS made recently in the East are decided proof that it will pay to pick out the most perfect potatoes for seed, no matter what the price may be, and that it is a losing game to plant the refuse tubers.

THE Healdsburg Flay says that in Russian River valley, and generally in Sonoma county, nearly every acre has been seeded, and the prospects for abundant crops were never more flattering.

THE Marysville Appeal of the 20th says: "Farmers who have been holding over hay for spring prices are now hauling it to market and the stables are supplying themselves at low rates."

A GRANN horse and cattle show is to be held at Petaluma April 3d, which will probably prove the grandest exhibition of the kind ever held in Sonoma county.

ALFALFA, in the opinion of the Yolo Mail, meets the demand of a grass that will withstand the hot sun, a parched earth, and the desiccating winds that sweep down the Yolo valley.

A GENTLEMAN reports to the Hollister Advance that the country south of there is prosperous, but the feed is none too plentiful for the large flocks on the range.

THE Foothill Tidings calls attention to the fact that the foothills of the State are admirably adapted for raising eumao, a material much used for tanning purposes.

THREE thousand acres in San Benito county are planted in flax.

UTAH has in successful operation thirty-one silver smelting furnaces, four arrastras, one separating and refining works, four concentrating works, and thirteen silver mills.

A NEW mining district has been organized in Napa county, and is called Schramburg.

Tapping a Shaft.

The Virginia *Enterprise* describes as follows the operation of tapping shaft No. 2 in the Sntro tunnel. The tapping of the water in shaft No. 2, Sntro tunnel, was yesterday successfully accomplished under the supervision of chief engineer of the work, Carl O. Wederkinch, a most accomplished young engineer. He had charge of the central shaft section of the Hoosac tunnel, and has had much experience in other large works of the kind. He took charge of the Sntro tunnel as chief engineer May 1, 1874, and has since been conducting that work. It will be remembered that on the 30th of June, 1874, the men were driven out of shaft No. 2 by the striking of a heavy body of water as they were drifting west from its bottom. The volume of water was too great to be handled by the pumps and the shaft, 1,040 feet in depth, was filled up to within 100 feet of its top. Work at that point was then suspended until the tunnel header should be advanced far enough to tap the immense body of water contained in the shaft. On the 8th instant the regular work of driving the header of the tunnel was suspended, being at a distance of 8,800 feet from the mouth of the tunnel and 98 feet from the water in shaft No. 2. A diamond drill was mounted and adjusted by Mr. Wederkinch, with the aid of a transit instrument in obtaining the line and a leveling instrument for the grade, in order to exactly strike the header driven east from shaft No. 2. A double bulkhead, built of 12-inch timbers was constructed between the drilling machine and the face of the tunnel, with a quarter-inch boiler-plate slide arranged vertically in its center. Drilling was begun on the 9th instant at 11 o'clock P. M., the power for the drill being compressed air. It made its way through the unusually hard rock at an average speed of 18 inches every 15 minutes, diameter of hole being 2 inches. Excepting one interruption of several hours caused by the breaking of the diamond bit, the drilling went on finely, and on March 11, at 2 A. M., three times three cheers were heard from all when the drill-rod broke through. The water coming out at the side of the rod under a head of 835 feet (to which the water had lowered since June), was white as snow, and quite hard to feel of. Great care was taken in letting back the drill-rod, but after a few feet had come out, the friction between the machine and rod and the grip of every man present was no longer sufficient. It went, like a streak of lightning, even not lacking the fiery part, and finally lodged back in the tunnel. The plate, in the middle of the bulkhead went down in front of the hole, changing the 120 inches of water coming out into a beautiful white feathery-shaped fountain. The idea of striking the workings of No. 2 shaft by a diamond drill through 100 feet of rock, at a distance of one and two-thirds miles from the mouth of the tunnel, has been doubted by most every one; its successful termination establishes here the already well-earned name that Mr. Wederkinch has attained by his accurate work on the Hoosac tunnel and in other places. In three hours the water had been lowered in the shaft 128 feet. Last evening, however, we were informed that the flow had ceased. It is supposed that the drill hole is stopped up by a piece of rock, or that a stick of timber has been sucked tightly against it. This obstruction, whatever it may be, will doubtless be shortly removed.

MACHINERY FOR THE MINES.—A large amount of machinery is now arriving almost daily for mines along the Comstock lode. Yesterday there arrived for the Silver Hill mining company a Corliss engine, said to be the largest engine of the kind on the Comstock. The frame or bed of the engine alone weighs 25,000 pounds. There were two car-loads of the machinery and its aggregate weight was 40,000 pounds. Two car-loads of machinery consisting of a steam chest, pump column, etc., arrived for the Florida mining company. Two car-loads of new machinery also arrived for the Utah mining company, making four car-loads received by that company during the past two days. Among the machinery received yesterday was a shaft weighing 7,620 pounds. The Consolidated Virginia mining company yesterday received one pinion and two spur wheels for their big mill, the weight of which was 5,870 pounds. There also arrived for the Gould & Curry company a lot of seventy-two strap plates, weighing in the aggregate 16,000 pounds. Thus is machinery of all kinds, from a large steam engine down to a small wheel or shaft, rolling in from the huge machine shops and foundries of San Francisco. This is all in addition to the vast amount of work of all kinds turned out by the several foundries, machine shops and boiler shops of this city and Gold Hill. Much machinery in the shape of air compressors, blowers, Burleigh and other drills of that kind, is brought here from the Atlantic States, while we have steel-wire cables and many other things from Europe.—*Enterprise*.

SPEAKING of the large number of immigrants arriving in Virginia City, the *Enterprise* says: "Not one in ten of these people are of any use here. They know nothing of mining, and many of them are without any trade. Why farmers and men who have all their lives been engaged in similar occupations should rush to our mines it is hard to understand."

PARTIES are already making their arrangements for extensive salt manufacture at Corrine, as soon as the spring opens.

South Mountain

A correspondent of the Idaho *Avalanche* writes from South Mountain a letter from which we make the following extracts:

The operations of the smelting works for the month of February have been light compared with what can and will be done in future. As stated in a previous letter the new furnace was put in operation on the 7th ult., and for want of coal shut down on the 18th. On account of the moisture of the new furnace, the first three days' operations amounted to nothing; consequently there were but nine days that produced any other results than the drying of the furnace. In these nine days two hundred and sixty tons of ore were put through, producing a little more than thirty-eight tons of bullion, containing:

Silver.....	\$13,292.53
And Lead.....	3,040.00
Aggregating.....	\$16,332.53
The cost of mining, transporting the ore to furnace and smelting is not more than \$22.50 per ton—260 tons make.....	\$5,850.00
Leaving the sum of.....	\$10,482.53
From which we subtract freight to San Francisco on 38 tons at \$40 per ton.....	\$1,520.00
And there is a balance and profit of.....	\$8,962.53
Or nearly \$1,000 per day on one furnace	

The Coal

Used heretofore has been principally from fir timber. Juniper is said to make a much better article and will be used mainly hereafter. The cost of coal will be much less, as well as the quality improved next summer. Now teams that draw it to the sheds have their work to do in and over deep snow, and have to be fed on hay and grain at high figures. Next summer they will have good roads to work on, and the rich grasses of a "thousand hills" to feed upon; consequently the cost of transportation from the pits will be greatly reduced.

All the Ledges

So far worked or prospected cluster around the town of South Mountain, but I am informed by those who explored the country when the ground was clear of snow, for a distance of six miles to the east there is a continuous range of metal-bearing ledges sure to be developed during the coming summer, and that as you go east this quality of precious metals increases while the quality of base metals decreases.

The Jetty System.

Among the closing acts of Congress was a large appropriation for applying the jetty system for deepening and keeping open the mouth of the Mississippi river. In this connection it may be interesting to learn what the application of this system has done for improving the navigation of some of the principal rivers of Europe. We copy from an exchange:

The month of the river Liban in Russia had six feet of water before the introduction of the jetty system and 16 feet of water after its completion. The river Pernau in Russia, six feet before and 16 feet afterward. The river Warne in Prussia had six feet of water before the introduction of the jetty system, and 13 feet afterward. The river Niemen in Prussia had at its mouth a depth of only ten feet before the jettees were applied, but afterward and up to the present time the depth of the water has been 23 to 24 feet. The river Pregel in Prussia had 12 feet of water before the application of the jettees, and now has 20 feet, though the improvement is not yet completed. The river Oder in Prussia had seven feet of water before the jettees were applied, and now it has 23 to 24 feet. The jettees there are permanent in their character. The river Danube, the mouth of which is very similar to that of the Mississippi, had nine feet of water before the application of the jetty system, and now has 21½ feet. The river Trave in Prussia had seven feet of water before jettees were constructed, and it now has 18.

MEXICAN MINES.—A correspondent of the *Bulletin*, writing from Mazatlan, says: The scarcity and dearthness of quicksilver is apparently the reason why this port is going to lose most of its trade. With the exception of the Tajo mine, near El Rosario, the Alacran at Copala, and Tamazulu near Culiacan, almost all the work in the other mining districts had to be stopped, and particularly at Cosala, the whole population is bankrupt, no returns coming from there for sometime. Fortunately the reports from Guadalcacer in San Luis Potosi, and from Huizotco in Guerrero, are very favorable, and as equally valuable cinnabar mines have been discovered in other parts of the world, it is to be hoped that the price of quicksilver will lower. At Oaxaca and at Culiacan the mines have imitated the California style of working on shares instead of the twenty-four barres, in which a mine used to be divided. The companies issue from 6 to 3,000 shares, and their value is daily quoted at the exchange; however, the principle has already been adopted some time ago in the City of Mexico, where a regular stock exchange exists. It is only something new in the minor places. The mining reports from Sonora and Lower California are very favorable, and no Indian aggressions are reported from the American frontier.

The sulphuret reduction works being erected near Nevada City are nearly completed.

Estimating the Value of Quartz Specimens.

Down at the banking rooms of the late A. Delano, as Superintendent Snyder from day to day brings up examples of the gold quartz coming out of the New York Hill mine, there is a great deal of guessing and estimating on the value of gold in the different pieces. There is a rule for ascertaining very closely the percentage of gold in a mixture of gold and quartz, and we have taken pains to condense and simplify from several metallurgical works before us as follows:

First ascertain the specific gravity of the gold specimen, by weighing it first in air, and then suspended by a fibre of silk, in water, and dividing the weight in air by the difference. Suppose it to be 8.067. The specific gravity of gold is 19.000; that of quartz is 2.600.

A. Deduct the specific gravity of the specimen from the specific gravity of the gold; the difference is the ratio of the quartz by volume: 19.000—8.067=10.933.

B. Deduct the specific gravity of the quartz from the specific gravity of the specimen; the difference is the ratio of the gold by volume: 8.067—2.600=5.467.

C. Add these ratios together, and proceed by the rule of proportion. The product is the percentage of gold by bulk:

$$10.933 \div 5.467 = 16.400$$

$$16.4 \text{ is to } 5.467 \text{ as } 100 \text{ is to } 33.35$$

D. Multiply the percentage of gold by bulk, by its specific gravity. The product is the ratio of the gold in the mixture by weight:

$$33.35 \times 19.000 = 633.65$$

E. Multiply the percentage of quartz by bulk, by its specific gravity. The product is the ratio of the quartz in the mixture by weight:

$$66.65 \times 2.600 = 173.29$$

F. To find the percentage, add these ratios together, and proceed by the rule of proportion: 633.65 ÷ 173.29 = 806.94.

$$806.94 \text{ is to } 633.65 \text{ as } 100 \text{ is to } 78.35$$

Hence a mixture of quartz and gold, having the specific gravity of 8.067, contains 78.35 per cent. of gold by weight.—*Foothill Tidings*.

MINERAL CHARACTER OF PUBLIC LANDS.—An opinion of the Supreme Court, in the case of *McLanghlin vs. Powell*, recently filed, in which the question of proving the mineral character of public lands is decided, and which contains a point that may be of interest to parties in this district. The court holds that in an action for the possession of patented lands, wherein the mineral lands are excepted, while the plaintiff may not be required to prove the non-mineral character of the land, the defendant must be permitted to establish that the lands sued for are within the exception. The reverse was the ruling of the court below, and upon this point the Supreme Court reversed the judgment, and remanded the case for a new trial. The opinion is by McKinstry.—*Stockton Independent*.

PROSPECT MOUNTAIN.—From S. J. Beebe we learn that considerable work is being done on the western slope of this lofty range. On the Manhattan claim, which was located in 1869, an incline has been opened from the bottom of the main shaft, and a pipe vein about two feet in diameter has been exposed, the ore of which assays from \$120 to \$160. The Cloud ledge has been opened to a depth of 50 feet, and several tons of excellent smelting ore have been extracted, assaying about \$80 in silver, with 50 per cent. lead. Work is still being prosecuted with advantage on the Williams mine, the Star, and several others. If the owners could only get a fair price for their ore, so that they might be enabled to meet current expenses, several valuable mines would soon be developed.—*Eureka Sentinel*.

A PONY MILL.—A neat mill, capable of reducing three tons of ore per day, has just been erected in Lower Gold Hill by Mr. Charles Feuerer, a man who has had much practical experience in milling. This little mill will be of great use in making working tests of ore for new mining companies and in working for men who own small veins containing occasional pockets of rich rock. In the vicinity of Silver City there are many small leads of gold-bearing quartz, in working which poor men might make very good wages provided there was a place where they could get their ore speedily and honorably worked whenever they had accumulated a lot of from ten to fifty tons. A mill supplying this want should do a good business.—*Enterprise*.

The fever created by the mineral development at Newburyport, Mass., is such that the Newburyport *Herald* says: "Pasture lands which stood on the assessor's books at \$8 an acre have actually been sold at about \$2000 an acre where there had been no ore found, but merely from the fact that they were adjoining the mine, and in a line with the vein which has been determined."

HEAVY BLAST.—Thirteen thousand and one hundred pounds of Santa Cruz powder was exploded in the Enterprise mine at Sucker Flat on the 18th inst., preparing a large quantity of gravel for washing.

The quicksilver mines in San Luis Obispo county produced 500 flasks last month. An additional mine will start a furnace soon, when the yield will aggregate not less than 900 flasks monthly.

The Livermore Coal Mine.

The Livermore *Enterprise* says: On Sunday morning we took a run up to the Livermore coal mine. Superintendent Thomas Harris escorted us to the newly discovered vein of coal, which is located about two hundred yards to the north of his residence, and there gave us all the information necessary on the occasion. The shaft was started about five feet square and at an angle of forty degrees incline. It follows a heavy hanging wall of arm sandstone, which passes through the hill from east to west and pitches to the north. The seam of coal was very light at first, but at a depth of fifteen feet commenced to be compact and took body. From this point till they reached about thirty-five feet, the vein increased in size until it became three feet, the hanging wall becoming as smooth and solid as granite, and the foot-wall well defined. But little if any dirt next to the coal. At fifty feet the strata had widened to five feet of very clear, glossy coal. But little water here so far troubled the workmen in their descent, and they are enabled to work rapidly and to great advantage. On top of ground there was upward of twenty tons of coal ready for shipment. The company are arranging to erect suitable hoisting works and prosecute the sinking of their shaft to a depth of perhaps two hundred feet.

It is a matter not to be doubted now that a heavy body of coal has been found in this new mine, and the company are assured by experienced coal miners that thousands of tons are in sight. We think as soon as the proper hoisting works are erected and other necessary machinery placed upon the ground, work will be pushed to great pecuniary advantage. At present our people generally feel highly elated over the prospects of the mine, and confidence in its beneficial advantages to our town is gaining strength. The shaft on Friday morning had reached a depth of 110 feet, with the vein still increasing in width, and coal improving in quality.

The Monroe mine is the name given to the quartz lode lately taken up by Messrs. Getchall, Mosher & Campbell at the Lone Tree, above Wheatland. Samples of the rock have been taken to San Francisco for assay, and the owners expect rich returns.

MONTANA is using its first Burleigh drill, introduced there by the National Mining Company at Unionville.

Varney's Patent Amalgamator.
These Machines Stand Unrivaled.
For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repair. The constant and increasing de-
mand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.
The pan being filled, the motion of the miller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces. —
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular row between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.
Settlers made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.
Mill-men are invited to examine these pans and settlers
for themselves, at the office, 229 Fremont Street,
San Francisco

This is a Sure Cure for Scraw Worm, Scab
and Foot Rot in Sheep. It also kills Ticks,
Lice, and all Parasites that infest Sheep.
Prevents scratching and greatly improves the quality
of the wool. One gallon of the Dip properly diluted
with water will be sufficient to dip one hundred sheep,
so that the cost of dipping is a mere trifle, and sheep
owners will find that they are amply repaid by the im-
proved health of their flocks.
The Dip is guaranteed to cure when used according
to directions, and to be vastly superior to Corrosive
Sublimates, Sulphur, Tobacco, and other remedies which
have heretofore been used by farmers.
Circulars sent, post paid, upon application, giving
full directions for its use, also certificates of prominent
sheep growers who have used large quantities of the
Dip, and pronounced it the most effective and reliable
known Cure and Preventive of Scab and other kindred
diseases in Sheep. mrl3-hp

Quartz Mill for Sale

At Mineral Hill, Elko County, Nevada, four miles from
Mineral Hill Station, on the Palisade and Eureka Rail-
road, and 35 miles from the Central Pacific Railroad.

The Mineral Hill Silver Mines Company (Limited
offer for sale their new 20-stamp mill (dry crushing)
built by H. J. Booth & Co. of San Francisco.

The mill is complete in every respect, with engine,
Boilers, Stetefeldt Furnace and all modern appliances,
and is as good as new, having only run two months
upon ore.

The whole is offered very cheap for cash. For further
information apply to

H. H. OAKES, Superintendent.
Mineral Hill, Nevada.

TO COPPER SMELTERS, BLUE-STONE and Sulphuric Acid Manufacturers.

For sale or to lease, the LEVIATHAN COPPER
MINE, in Alpine county, California.

The ore, which is in the form of silicite, black and
red oxide, and gray sulphide, with metallic copper
finely disseminated, averages from two to five feet
thick, and is 50 per cent. copper. A few parcels
taken out during exploratory operations realized \$30-
000 for Bluestone. In eight, 2,000 tons 20 per cent. ore;
on dump, 800 tons 5 per cent. Supply inexhaustible.
Title perfect. Minimum present capacity, 10 tons per
day, which may be extended indefinitely. Cost of
extraction, \$1. There is also a stratum of sandstone 20
feet in thickness, impregnated with 25 per cent. of
pure sulphur. To a coin purchaser highly advantage-
ous terms will be offered. For further particulars
apply to Louis Chalmers, Silver Mountain, Alpine
county, Cal.

Ayer's Hair Vigor

RESTORING GRAY HAIR
TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sick-
ness, care, disappoint-
ment, and hereditary
predilection, all turn
the hair gray, and either
of them incline it to shed
prematurely.

AYER'S HAIR VIGOR, by
long and extensive use,
has proven that it stops
the falling of the hair
immediately, often re-
news the growth, and always surely restores its color,
when faded or gray. It stimulates the nutritive organs
to healthy activity, and preserves both the hair and its
beauty. Thus brassy, weak or sickly hair becomes
glossy, pliable and strengthened; lost hair regrows with
lively expression; falling hair is checked and stabled;
thin hair thickens; and faded or gray hair regains their
original color. Its operation is sure and harmless. It
cures dandruff, heals all humors, and keeps the scalp
cool, clean and soft—under which conditions, diseases
of the scalp are impossible.
As a dressing for ladies' hair, the Vigor is praised for
its grateful and agreeable perfume, and valued for the
soft luster and richness of tone it imparts.

507 MECHANICAL MOVEMENTS,
Illustrated and described.

Inventors, model makers and amateur mechanics
and students, will find the work valuable far beyond
its cost. Published by DEWEY & Co., Patent Agents
and publishers of the Mining and Scientific Press.
Price, post paid, \$1.

MINING AND SCIENTIFIC PRESS.—Unquestionably the
best mining paper in America for those interested in
gold or silver, placer or quartz mining, is the MINING
AND SCIENTIFIC PRESS, published by DEWEY & Co., San
Francisco, terms \$1 (gold coin) per annum. It is de-
voted especially to mining affairs, has an able corps of
editors and correspondents, publishes all important
legislation relating to mining matters, investigates and
produces with illustrations the new machinery and
processes of mining and reducing, and kindred sub-
jects, and gives full account of operations in the Pacific
States and Territories. There is scarcely anything
published in it but what is of interest to miners, and
local papers can reproduce but little of this matter,
and that without illustrations. —New North West.

Upright Safety Engines and Boilers.
(IMPROVED)
(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call your attention to the practical and simple mechanism of this Engine Boiler; the in form not only pleasing to the eye, but also, that which secures the greatest strength and rigidity with a minimum of weight. The style with internal fire box, and a light tubular boiler, with a grate area of 160 square feet, and a heating surface of 1600 square feet, and it is actually unnecessary to purchase a greater rated power than is actually required, while in case of emergency these boilers can be depended on for more than their rated power. The engine is not affected by expansion, nor are the bearings over-heated by condensation, or the heat from the boiler. The fly-wheel being at the base secures a perfect steadiness under the high speed which is necessary for economy of fuel. All parts are easily accessible—a great advantage. It is complete in itself as a Portable Engine and Boiler, or the boiler can be detached from the engine, and the engine can be used for pumping, or for other purposes. The engine is simple, safe and economical. For printing offices, laundries, tanneries, ranches, small repair or machine shops, or for hoisting, wherever a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

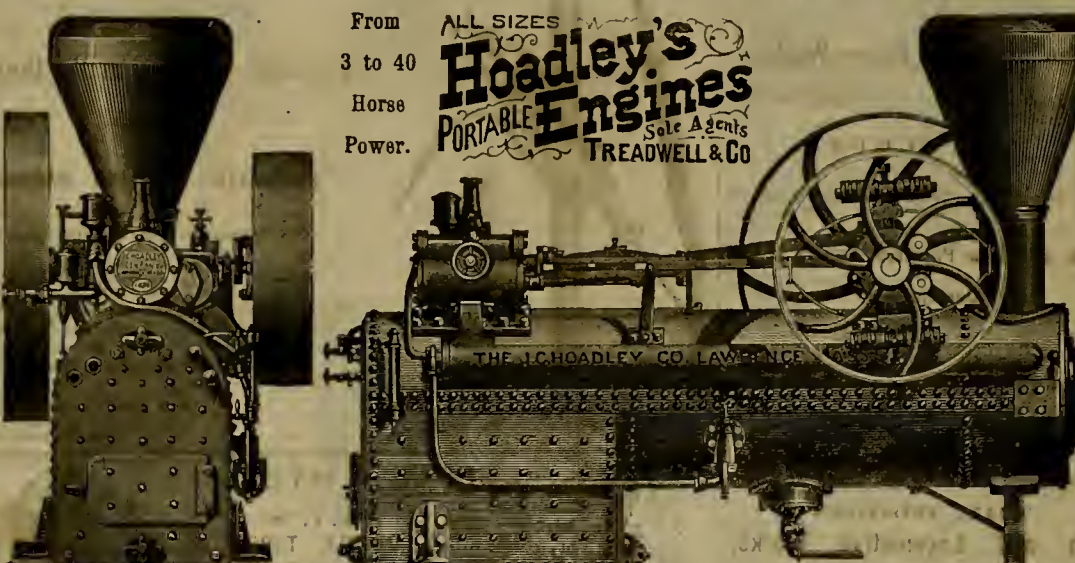

TREADWELL & CO., Sole Agents, S. F.

THE "HOADLEY" PORTABLE STEAM ENGINE

From **ALL SIZES**
3 to 40
Horse
Power.

Hoadley's Portable Engines
Sole Agents
TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell Endshake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine.

Millions, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

TREADWELL & CO., San Francisco.

DEWEY & CO.,
American & Foreign Patent Agents,

The best, speediest, and surest method for you to obtain patents, file caveats, or transact any other important business with the Patent Office at Washington, or with foreign countries, is through the agency of DEWEY & CO., PUBLISHERS OF THE MINING AND SCIENTIFIC PRESS, SAN FRANCISCO, an able, responsible, and long-established firm, and the principal agents on this side of the continent. They refer to the thousands of inventors who have patronized them, and to all prominent business men of the Pacific Coast, who are more or less familiar with their reputation as straightforward journalists and patent solicitors and counsellors. We not only more readily apprehend the points and secure much more fully and quickly the patents for our home inventors, but with the influence of our carefully read and extensively circulated journals, we are enabled to illustrate the intrinsic merits of good patents, and secure a due reward to the inventor, besides serving the public who are more ready to give a fair trial, and adopt a good thing, upon the recommendation of honest and intelligent publishers.

To Obtain a Patent,
well-constructed model is generally first needed, if the invention can well be thus illustrated. It must not exceed 12 inches in length or height. When practicable, a smaller model is even more desirable. Paint or engrave the name of the article, and the name of the inventor, and his address upon it. and the model (by express or other reliable conveyance), plainly addressed, to "DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, SAN FRANCISCO." At the same time, send a full description, embodying all the ideas and claims of the inventor respecting the improvement describing the various parts and their operations. Also send \$15 currency, amount of first fee of the Government. The case will be placed on our regular file, the drawings executed, and the documents made up, and soon sent to the inventor for signing. As soon as signed and returned to us with the fees then due us, it will be sent straightway to the Patent Office at Washington or designs no models are necessary. Duplicate drawings are required, and the specifications and other papers should be made up with care and accuracy. In some instances for design patents two photographs, with the negative, answer well instead of drawings, or for further information, send a stamp for our illustrated circular, containing a digest of PATENT LAWS, 112 illustrated mechanical movements, and HINTS and INSTRUCTIONS regarding the RIGHTS and PRIVILEGES of inventors and patentees, which will be furnished post paid. Also a copy of NEW PATENT LAW of 1870: When the invention consists of a new article of manufacture, a medicine, or a new composition, sufficient to make the experiment (unless they are of a common and well-known character), and also of the manufactured article itself, must be furnished, with full description of the entire preparation. or Processes, frequently no model or drawings are necessary. In such case, the applicant has only to send us an exact description, and what is desirable to claim.

Designing and Engraving at This Office.
We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machinery, Works of Art, Manufactured Articles, Trade Marks, Seals, Etc. We have a first-class **Machine for Engraving**
A portion of the work, which can be finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can be seen at our office.
DEWEY & CO.

The Large Circulation of the Mining and Scientific Press extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the Continent. Its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

A GOOD PAPER.—THE MINING AND SCIENTIFIC PRESS has entered its 30th volume. It grows better as the years roll, and it, without exception, the best paper published for California miners and artisans. If such papers were more generally circulated to the exclusion of the sensation trash of the cities, the State would be the gainer in wealth, morals, and general intelligence. —*Tuolumne Independent.*

No AGENTS are authorized to receive subscriptions for this paper at less than our advertised rates.
GEORGE WILSON, formerly contributor of the MINING AND SCIENTIFIC PRESS, will please address this office.

LOOK TO YOUR INTEREST!

IS THE
RUBBER PAINT.
Patented June 22, 1869, and April 4, 1871.

MANUFACTURED BY THE
PACIFIC RUBBER PAINT COMPANY.
For many years chemists and others have experimented in mixing India Rubber with Oil, Lead, etc., in order to produce a perfectly
WATER-PROOF PAINT,
And at last successful in their effort, have formed a chemical combination of Rubber with oil paints, which when applied becomes hard and elastic enough not to crack or peel, from the action of the atmosphere, with a gloss equal to work finished with varnish. The
Pacific Rubber Paint Company,
Of San Francisco, California, together with the RUBBER PAINT COMPANY, of Cleveland, Ohio, own all the patents covering perfect combinations like the above, which is known and sold by them as "Rubber Paint."
The great demand for the Rubber Paint induced this Company to purchase of the Cleveland, Ohio, and New York Rubber Paint Company, the patents for this coast, and are now manufacturing this paint in all colors, in large quantities, and have put the price below the lead and oil paints. The Rubber Paint is prepared in Pure White, in all tints and other colors, comprising any number of different shades and put up ready for use, being a great advantage, as it can be spread by any one.
It Flows From the Brush Freely, Works Easily, and Settles Promptly. It is available for all kinds of Painting, And may be used with equal advantage on iron, stone, wood, brick, or plaster.
The Rubber Paint will cover more surface, cover it better, and last much longer than Lead and Oil. Two coats of the Rubber Paint is better than three coats of Ordinary Paint.

REFERENCE:
SAN JOSE, CAL., March 20, 1875.
PACIFIC RUBBER PAINT CO., San Francisco.—Gentlemen:—I have used and sold the Rubber Paint in this city during the last four years. We have about one hundred buildings painted with the Rubber Paint. Among the prominent ones are the State Normal School, Gates Institute, City Market; the residences of Josiah Beiden, J. V. Hinds, President Gold Note Bank, J. B. Arguello, Santa Clara, etc. It has never failed to give satisfaction, with a test of from one to four years, so that its durability has been well tested. My sales last year were nearly five thousand gallons.
Truly Yours,
AMASA EATON.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cups; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 123 First street, S. F. 24x23

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor, also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

D. B. MILLER & CO.,

No. 12 West Eighth Street, Cincinnati, Ohio

GIANT POWDER.

The Giant Powder Company own
U.S. Letters Patent for all Nitro-
Glycerine Powders.

The object of this Company, since the Powder was first introduced, has been to make their Powder as perfect as possible.

Late improvements, made by the Chemists of the Company, have enabled us to produce a still stronger Powder than heretofore, and overcoming as much as possible the effects of the gases which are evolved by the explosion.

We therefore assure the public that the Giant Powder is now superior to any other Blasting Material, notwithstanding what those who are infringing on our patent rights, may say to the contrary.

We respectfully call upon those dealing in or using Explosives to sustain our Company, which alone have the right to manufacture or sell Nitro-Glycerine Powders.

The great success this Powder met with and the favor it found among all Consumers has emboldened others to produce a similar article, thereby infringing on the GIANT POWDER COMPANY'S Rights, and forcing a prosecution against those Manufacturers as well as Consumers.

We offer the Giant Powder at the **LOWEST RATES** fixed by the Company.

Also for sale the best electric Exploders, made at the Company's Works, in the Eastern States.

Single and treple force Giant Powder Caps, and Fuse of the different Fuse Manufactories constantly on hand at the lowest prices.

Number 14

Improvement in Screw Propellers.

The frequency with which propeller blades have been lost from different steamers during the past year or two has provoked considerable discussion and comment, and many people question whether the propellers can be made strong enough to stand the strain on large vessels. The *City of Peking* lost two blades of her propeller on her voyage from New York to this port, and after they were repaired she lost one more in her first voyage from here to China. The *City of Tokio*, a sister ship to the *City of Peking*, also lost one blade of her propeller in her voyage from New York to San Francisco. Both of these vessels are very large, and would be unwieldy under sail alone, so that the confidence inspired by the size becomes lessened when the liability to breakage of the propeller blades is considered. Inventors have been for some time past trying to devise some plan which would overcome this difficulty in connection with propellers, and many suggestions have been offered. The conclusion arrived at by some as to the cause of these accidents, is that the blades are given too much pitch, and that in order to get a large propelling surface the consideration of safety to the propeller is ignored. With an immense vessel like the *City of Peking*, for instance, with very heavy and powerful machinery, the strain on the blades is very great. When she meets a heavy sea, and her headway is denuded for the moment, with the engines still working, the strain on the propeller is suddenly and greatly increased. The greater the flare or "pitch" to the propeller blade the greater the strain in such a case. When the vessel is going ahead smoothly of course it is different, but when we think of what the screw has to bear in a heavy gale, the only wonder is that propellers stand as much as they do.

Steam vessels are usually poorly supplied with gear for sailing, and the serious results which arise from breaking a propeller should an accident happen during a gale, are easily imagined. Among the devices intended to counteract the tendency to breakage is the one shown on this page, which was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Mr. James H. Loftus, of Oakland. This construction, while it renders it easy to remove any blade, should it become necessary, is intended more particularly to prevent the breaking of the blades at what is usually a weak point, the shank, about a foot or so from the hub.

In this invention the main blade, A, is made of a suitable material and thickness, and it is strengthened in its weaker points by the addition of shorter leaves, of which any number may be used that are desirable. In our illustration two extra leaves are shown upon the back, and one upon the front of the main blade. The main blade is bent at right angles at the end next the hub, and fits into a groove planed into this hub, as can be seen in Fig. 2. The front supplemental leaf is bent in the same direction, while the two rear leaves are bent in the opposite direction, thus forming a strong base, which fits solidly into the groove in the hub.

Each of the blades is fitted in the same manner, and the whole are held in place by means of clamping rings or hands (shown at B) which are driven on from each end of the hub.

THE CONSOLIDATED VIRGINIA mine is yielding 450 tons of ore daily. The ore breaks on the 1300, 1400 and 1500-foot levels of the mine are looking splendidly, and show no signs whatever of the diminution of the regular daily yield. The bullion yield for the month of March was increased to nearly a million and a half.

CROSS CUTTING on the 1700-foot level of the Ophir mine is being prosecuted with all the energy possible, with some very favorable indications of an ore development in the east cross-cut on the California line.

Hydraulic Mining in California.

No. 19.

The Extraction of Gold.

Quicksilver is used to collect and combine small particles of gold, in the form of amalgam. To facilitate this action it is necessary to use it in such a way that it may be constantly exposed to a contact with these minute particles of gold. For this reason the washing through the sluice-boxes must commence before any quicksilver is used, so as to get the interstices between the riffles filled with small gravel, sand, clay, &c.

This washing without quicksilver may be carried on for a day, and light top-gravel will be the best material to use.

After the openings in the different riffles are thus filled, so as to prevent the quicksilver from dropping clear to the bottom of the sluices, it may be applied, for the first charge,

a year, when the whole line of sluices is deprived of its gold and quicksilver.

The riffles, whatever they may be, are put alongside the sluices, ready to be replaced for new service.

Cleaning the Amalgam.

The amalgam must be placed in a quicksilver bath to separate the gold from any baser metal, particularly lead, which has been scattered by the hundred pounds over the hill-sides of California by quail and rabbit hunters. The amalgam must be well broken up, and rubbed and washed repeatedly. In this way the gold, as the heaviest part, will settle to the bottom, and all the other metallic substances will float on the top of the quicksilver. After this washing the amalgam is deprived of the free quicksilver by straining through a filter of canvas, and afterwards put in a bath of water and sulphuric acid (one-third acid and two-thirds water) and bailed and stirred over a slow fire for about forty minutes. By this process the remaining lead is generally removed, and the

LOFTUS' IMPROVED SCREW PROPELLER.

with a liberal hand. From 500 to 600 pounds are used for a sluice of 5,000 feet length. The upper parts of the sluice are generally charged more profusely than the lower parts, as a portion of the quicksilver is carried down by the stream.

The quicksilver must be scattered in a light spray all along the sluices; iron sprinkling-pots, made for the purpose, are used with good effect. The charging of the sluices is generally attended to twice a day; but it must be admitted that a more liberal and more frequent application of quicksilver would be only beneficial. The daily charges of quicksilver are reduced to about 100 pounds, so that a supply of one hundred flasks of quicksilver (about 74 pounds per flask) will last for a six months' run, allowing for the quicksilver regained by the semi-monthly cleaning up of the upper part of the sluice-boxes.

Cleaning Up.

The upper part of the sluice, provided with either scantling-riffles or block-riffles, is generally cleaned up once or twice per month. Whenever this is resolved upon the sluices are gradually emptied of their gravel contents down to the riffles, and these are removed successively, commencing with the upper riffle.

A small stream of water is applied to move gently the black sand, or fine gravel, which may remain in the sluices. The amalgam or quicksilver is scooped up and put in wooden or iron buckets. Here and there pieces of scantling are placed across the sluice to check the flow of the quicksilver. Brooms, scrapers, and knives are used to collect the amalgam which may hide in small fissures of the wood. A general cleaning up takes place once or twice

The Tenth Industrial Exhibition.

All the preliminary arrangements are being rapidly made for the Tenth Industrial Exhibition of the Mechanics' Institute of this city. Mr. J. H. Culver has been appointed Agent for this exhibition, and has commenced to call on parties who intend to make displays. Mr. Culver has been connected in an official capacity with several of these exhibitions, and is well known among us. Blank applications for space can be procured at No. 27 Post street, and it is important that these applications be sent in as soon as possible. The exhibition will open on the 17th of August.

It is to be hoped that our manufacturers and artisans will, for the credit of the city, unite with the miscellaneous exhibitors, and make the exhibition a worthy one. The display of machinery at the last Mechanics' Fair was a meagre one, and not at all in proportion to the interest represented. At that time our foundrymen and mechanics were all very busy, and were unable to do as much for the exhibition as they desired. They are busy now, too, but have nearly five months time to prepare such articles as they intend to display. They should accordingly begin right away, and make up their minds what to do—and do it. We hope to see a display of machinery this year, which will throw in the shade all previous efforts.

Some of the manufacturers complain that the fair is more of a Fair than an Industrial Exhibition. But they must remember that the managers are compelled by force of circumstances to rely entirely on the manufacturers and artisans to bring it up to the proper standard. If it is not as much of an Industrial Exhibition as a fair, it is the fault of the manufacturers, and not the managers. The latter provide the space, light, power and spectators. The manufacturers ought to provide the objects of attraction. A great many, of course, attend these exhibitions to see, and be seen; but still there are thousands interested in the machinery department, who would spend their whole time there if this department was filled. This part of the exhibition is by far the most interesting to many, and our foundrymen ought to "keep up their end," and make a creditable show. They have been prosperous of late, and can afford to sacrifice a little time to this matter. They should remember also, that they could not possibly find a better way of advertising, and should by all means take advantage of the opportunity.

RANSOME STONE.—Mr. Ernest L. Ransome has commenced the manufacture of Ransome stone in this city, on his own account and by a new process. The stone was formerly made by the Pacific stone company, but it was found that the cost of manufacture was prohibitory, and the company retired from business. Mr. Ransome now has a new patent and can manufacture a good article as cheap as any other manufactured stone. Mr. Ransome's office is No. 10 Bush street and the factory is on Octavia street, near Greenwich. The Ransome was the first artificial stone used on this coast, and Dr. Stone's church was the first building upon which it was used. Every style and character of stone work is made by the process employed, some of the ornamental work being very handsome.

The Kimball manufacturing company has just completed four monster wool presses for the new wool warehouse, on Townsend street, two being for Ball & Julien and two for John F. Knox, Esq. The imported presses cost from \$1,200 to \$1,500 dollars each. The Kimball company manufacture an equally powerful press for \$750.

At the Mint in this city, during the month of March, the gold coinage was: Double eagles, \$2,180,000; half eagles, \$20,000. The silver coinage was: Half dollars, \$127,000; dimes, \$185,000; trade dollars, \$30,000. Total coinage, \$2,542,000.

The new retorts of the Amador quicksilver mine have been completed and are now in good running order, and the work of extracting the pure quicksilver is now under full headway.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner in Mining Statistics.

Owyhee Mines.

The lost issue of the *Owyhee Avalanche* gives a general review of the mines in that part of Idaho. For sometime these Idaho mines have been under a cloud, and assessment after assessment has been levied upon them. Judging, however, from the review of the *Avalanche*, the flattering developments made this winter in the Mahogany, South Chariot, Golden Chariot, War Eagle and other mines, in connection with the encouraging prospects of the base metal deposits in South Moutain, make it safe to predict that the bullion product of the coming summer will be a great deal larger than during any previous season. We condense the following items from the *Avalanche*:

Golden Chariot.

From Col. Keown, the veteran Superintendent of this mine, we learn that shafts are being sunk in both sections of the mine, including what was formerly known as the Minnesota. Four levels are also being driven. The Chariot shaft is down below the 11th station to a depth of 20 feet, and the Minnesota shaft is down 60 feet or more below the 10th, and towards the 11th station. The 10th level, Minnesota, is already in 75 feet south, and the 10th level, Chariot, is in 100 feet south towards the Linkton chimney. The 11th level, Chariot, is in southward about 14 feet, and the 11th level north just starting a few feet in. The developments thus far are very satisfactory. In a ledge encountered recently a very large, rich vein was found, and in one place in the 10th level Chariot it was found to be 7 feet in width. Operations are being pushed with all possible speed. Since the 21st of November more than 400 feet of shaft have been sunk, about 215 feet in the Minnesota and 191 feet in the Chariot, besides sinking two winzes and making explorations in the upper levels. The working force is not large, but will be increased in a short time.

The Golden Chariot mill will be in operation in a few weeks. It has been renovated and put in thorough repair during the winter, with new mortars, cams, tappets, etc. The mill is in much better condition now than it ever was before.

Ida Elmore.

Superintendent Corey reports main shaft now 26 feet below the 13th level (quite sufficient for pump). Work of sinking has been suspended, and soon as lower pump is in place and preparatory work done, attention to cross-cutting will be given at 11th, 12th and 13th levels, each new level being 120 feet in depth. New boilers work splendidly, and doing 25 per cent. more work with one third less wood than the old boilers.

The work of putting in place the 13th level pump is progressing well and approaching completion. Expect soon to be ready to commence opening new levels. New set of boilers now in mill and furnace is being built and connection made. In two weeks the mill will be ready to start up.

South Chariot.

Supt. Corey reports connection with Mahogany drift on 10th level. Eighth level cross-cut is in 47 feet, showing several strata of quartz, and considerable water in the face indicating near approach to the ledge. Winze No. 2 on this level is down 31 feet, showing a ledge of 15 inches wide of fair pay ore. This winze is north of the slip and within 80 feet of the Minnesota lode. It makes favorable showing for 9th level north. Ninth level drift is 27 feet north of winze No. 1, or almost 200 feet north of shaft, and has begun to show some very rich ore, although the vein is small, being from six to eight inches thick. It is steadily improving in size as the work progresses, and promises to prove an important development.

Mahogany.

On the 9th level, where drifts are already run, a nearly continuous body of ore is shown for 400 feet, and for an average width of 2½ feet. We are now opening up preparatory to opening out the ore, which at every point is of good quality and the ledge strongly and well defined. This level can be made to yield 5,000 tons of high grade ore. We are now taking out 12 tons of ore per day, which will soon be increased to 20.

Water sump below 11th level is nearly complete, the shaft being some 22 feet below station and crosscutting for ledge, which should be reached at a distance of about 28 feet, will be commenced now. Drift north on 10th level is now in a distance of 98 feet, and south drift on some level 73 feet, both carrying the same good ore, and strong, well-defined vein as heretofore reported. South drift on 9th level is in a distance of 439 feet. There is still another chute of ore further south, as shown by recent work in the 8th level, which the 9th level drift should reach about 30 feet further. The winze on 9th level is down 31 feet through good ore. The stopes on 9th and 10th levels now opening are all in fine ore, and promise a satisfactory yield, both as to quantity and quality.

War Eagle.

A rich body of ore has been struck in the northern portion of this mine, which gives good promise of being extensive. We were last evening shown a large specimen from the new find which was thoroughly permeated with gold and silver. It appears to be entirely different from any ore hitherto found in the

mine, and has a decidedly healthy look. Ore continues to be raised as usual from the mine, and hauled to the Golden Chariot mill.

Pauper.

Rapid progress is being made in the development of the Pauper, and a large amount of good pay ore can be extracted as soon as another level shall have been opened.

Empire.

In this mine they have commenced driving the 6th level drifts both north and south from the crosscut in a large vein of good ore, which promises to be richer and more extensive than any yet found in the mine. Empire is looking up.

A True Story of the Black Hills Excitement.

The Chicago *Journal* gives the following version, as the true story of the Black Hills excitement:

Situated in northwestern Wyoming, near the Nebraska and Dakota State line, are the Black Hills, of which so much has been said within the past few years, and over which a fever of excitement has been raised this spring throughout the Northwest, on account of the alleged existence there of gold and silver in fabulous quantities and easy of access. The hills spoken of are a cluster of volcanic elevations, detached from the Rocky mountains, and in comparison with the great and elevated peaks in the range proper, are but heaps of dirt. General Custer thoroughly penetrated this region last fall, and found that the vegetation there was ordinary in its growth, timber small and not over abundant, water scarce, and mineral wealth not remarkable. This, then, is the region to which the public is directed, and from which is promised a fortune for all who will take stock in the expeditions preparing to invade it. A region where there is gold to be had; gold, for Custer found indications of it; gold, for parties lately returned have it on exhibition. But the question of the existence of gold and silver is the only one which must be answered in seeking wealth by mining. Not "how much?" but "how attainable?" is the all-important point. The mountains of the West are full of gold, but men grow poor in getting it out. Not a stone, scarcely, is there in the whole Rocky mountain range that has not gold in it. Gold quartz is found on every side, holding with a flinty grasp its precious wealth, and the sand in all the streams that have a source in the mountains of the West, even in the Missouri river, hundreds of miles from its source, will "wash out" the coveted yellow dust at every pan. But gold in stones is gold in prison, and gold in quartz can only be got out with gold expended in "crushers" and "stamps" (machinery of great cost), while gold in the sands of rivers must be "washed out" by slow processes. The gold exhibited from the Black Hills is mostly in quartz, just the same article that fortunes have been sunk upon in Colorado these many years, in getting machinery to extract its yield; and as for the Black Hills "gold workings," it will take water, a scarce article in that region (see a map of the country) to get rich in that way.

But the question of those who are instigating the movement into the Black Hills is not "Is gold out there?" It is, "Can we get a rush of men through our cities, over our railroads, and a rush of money into our pockets?"

Two or three years ago the Black Hills were not dreamed of, even in Sioux City, Iowa, where now the seat of excitement is located. That city then relied upon its river commerce and its situation at the head of the Upper Missouri trade for its prosperity; but, in an evil hour to Sioux City, the Southern Dakota railroad was projected to Yankton, and the latter city became acknowledged as the coming shipping point for freights from railroad to steamboats. Sioux City's pulse ran low, and "What shall we do?" was the interrogatory uppermost in the minds of her citizens.

Back of Sioux City are high and precipitous bluffs, and one fine morning, soon after the Dakota Southern project became a fixed fact, the people of Sioux City and the strangers within her gates were electrified with the announcement that gold had been discovered in the bluff! It was heralded by mouth and telegraphed throughout the land; every soul was stirred, outsiders rushed in, and within a week's time the bluffs were driven full of stakes to mark off A, B and C's claims. Gold of wondrous richness was exhibited in store windows and carried around by interested parties. It was found abundantly in some claims in "vein" and in "pocket." Sioux city was happy. Business was lively. Money began to get "reckless." But the end came. At length, "close" some one discovered the secret. It was all a hoax! The bluffs had no more gold to them than a snow-drift. The big bonanza had been "altered."

This was Sioux City's excitement No. 1; and mark you, everybody, the leading men of the excitement then, are the leading men of the excitement now. "If such a little gold *furor* could make things so lively," the schemers soon began to argue, "why not get up a great excitement, and make us all rich?" And so they soon behought them of the Black Hills, on the point which would most naturally be reached by way of their town. No man had been seen from there, but still gold specimens were soon on exhibition (they had seen service before), purporting to have come from the region through traders and Indians. The business men were talked with in their stores,

and shown the advantages of such a scheme. They were asked to subscribe to send men East to "work up" an excitement. This was last year, and the expected "rush" did not "pave out" very well. Excitement No. 2, like No. 1, accomplished little. However, fate and hard times made it necessary that the coon be caught, and that a voice might be heard from the hills themselves, a party was sent out last winter, amply provided for and provisioned, to stay until the grand tide should set in. Two of the party came back ten days since, in the nick of time to start the ball rolling. One of the eye-witnesses is in Chicago now, accompanied by two of the champion gold-fever makers of the city of Sioux, and the ball has begun to roll—the ball which is meant, not to crush money out of the Black Hills, but out of the hot-headed men who become attacked with the fever.

Who pays the expense of the expeditions organized to come here and work? Ask the Sioux City merchants. Which way will they direct all expeditions? Through Sioux City, to be sure. How much per head will the Black Hills Association get for every man whom it sends over the Western railways? Ask those inside the ring.

The mystery that is surrounding the reports of riches in the Black Hills—the word of two men against the Custer expeditions alone being given—should deter men who have to work for a living from going on so wild a chase at the beck of unsubstantial rumors. Common sense will tell every man who has had experience in mining that there are no fortunes anywhere, in any gold fields, unaided by money and machinery. Added to this are the positive orders from the War Department to keep back all intruders from the land, ceded by treaty to the Sioux Indians. Who, in the face of all these facts, will consent to be led captive by an excitement worked up to further the selfish ends of unscrupulous parties.

TUOLUMNE COUNTY MINES.—The Tuolumne Independent says: The mines of Tuolumne offer many good chances for the investment of capital, and those below who know not what to do with their uninvested means, and prefer mining to other business, would do well to investigate the many good opportunities offered in this county. We would earnestly advise them, however, to come and see for themselves, or send those in whom they can implicitly trust, of good judgment and practical experience. Kid glove experts and adventurers on the make, are not wanted; for Tuolumne has suffered too much, in times past, by these fools and knaves. They have done more to injure our quartz interests than all other causes combined, and every man interested in the welfare of this county should have no dealings with such or their employers. We wish our mines represented on their merits alone, and by this only we wish them to rise or fall. As one among many instances of judicious investment in our mines and as an evidence that such opportunities exist, we may mention the Knox & Boyle. One-half of this mine was offered to parties if they would furnish the sum of \$25,000 to open and develop it.—The proposition was accepted, and after using only \$7,000 (the balance lies in bank) the mine was not only made self-sustaining but has and is paying handsome dividends, besides carrying on the work of extended developments. Judge Preston is Superintendent of this mine, and it is by having just such energetic and practical men in charge of several of our mines, that Tuolumne is gradually taking her proper place among the most noted lode-mining districts of the Pacific slope.

MINING DECISION.—The Secretary of the Interior on the 25th ult., made a final decision of the contest of the Bullion Mining company with the "420" Mining company, of Nevada. The former applied for a patent to the mine on the Comstock lode, and the latter filed an adverse claim. The Commissioner of the General Land Office decided that the Bullion company were entitled to a patent, and the case was appealed to the Secretary of the Interior. Meanwhile the case was carried into the Nevada Courts, which also decided in favor of the Bullion company, whereupon the "420" company took a writ of error to the U. S. Supreme Court, and claimed that the Secretary of the Interior should suspend proceedings to await the decision of that tribunal. Secretary Delano now holds that the U. S. Supreme Court has no jurisdiction over any contested mining case or writ of error after it has been adjudicated by the highest Court of the State or Territory in which the claim is situated. Being satisfied of the correctness of the Commissioner's decision, he therefore directs that a patent be issued to the Bullion company, in which a reservation shall be inserted reciting the fact that the surface ground described is the estimated area of the lode, and that only the usual surface ground embraced within the walls of the lode is intended to be connected. The Bullion company will thus get a patent for 943 feet along the lode, together with the surface ground that is bounded by the east and west walls thereof.

MARKING INK FOR LINEN.—Take the white of ten eggs, and beat them to a froth; to this add an equal quantity of water, and mix it well with comminuted uinnabar. As it is a tolerably thick liquid, pass it through a fine cloth, when it is ready for use. It is of a reddish color, and is set by pressing a hot iron over the wring side of the cloth as soon as dry. The hardest washing, acid or alkaline will not affect it.

Carpentry, Joining, Etc.

Carpentry and joining, though two distinct trades or arts, are usually combined in one; an expert in the two may be considered a builder. Carpentry consists in the assembling and fitting together, by framing, of pieces of timber whether large or small. It is distinguished from joining in the fact that the fitting is done without the use of other edge tools than the saw, the axe, the adze and chisel. The term carpenter originally referred to what is now called a wheelwright, and is derived from the Latin *Carpentum*—a car. The Latins called a wheelwright, *Carpentarius*. But the English word from the above derivation has now entirely lost its original significance.

A joiner is distinguished from a carpenter from the fact that his work is more nice and complex, and the plane, auger, etc., has to be added to his kit of tools, to enable him to meet the requirements of his calling. The joiner makes doors, window frames, stair cases, and the internal fittings, generally, of a house.

The one who shapes and frames timbers for the construction of buildings is sometimes called an artificer. An architect is one who plans and lays out the work, and superintends the building. He is a contriver rather than a worker. Architecture or the science of building, was one of the first arts taken up by man—next to providing food it was his first necessity. In the process of time it has become a visible art, and as an industrial pursuit, it is one of the most important in all the list of industries. It, perhaps, more than any other, measures the degree and progress of civilization; it is a pretty sure and the most significant visible index of the wealth and luxury of a people.

The California pioneer has had the rare privilege of witnessing the growth of a State from the primitive tent life, up through all its stages of cabin, shanty, cloth and paper, and balloon house, up to the magnificent palaces which are now beginning to adorn and beautify the streets and avenues of this Golden City of the far West—and all within the short period of only one quarter of a century! It is safe to say that history, nowhere, in all the centuries of the past, furnishes such another example of such regular and rapid growth. No one intervening phase of architectural progress has been omitted in our advance from the most primitive style of architecture up to the grandest and most perfect of any, even the oldest cities of the old world.

California seems to be forming a school of architecture peculiarly her own and one especially fitted to her local needs and conditions. She is also giving employment to an unusually large number of mechanics, in this direction, in proportion to her population. The class of dwellings now sought for by the working men of this city is also of a character altogether superior to those constructed for that class of people in our eastern cities, or in fact in any city, in the world. This comes from the fact of the larger degree of prosperity which attends the mechanic and working men here. Thus the rule already laid down, that the architecture of a people is a measure of their wealth and luxury, holds good here as well as elsewhere. San Francisco promises to become not only a city noted for the palaces of her millionaires, but also a city where the working man and mechanic are better housed than in any other city in the world.

Curiosities of Welding.

There has lately been shown in this country a very interesting specimen of blacksmith work. By means of Schierloh's welding compound, it is alleged that, in one example of bar of Bessemer steel, five different kinds of iron and steel have been perfectly welded, without changing its shape in the least. The bar was rolled into form at Thompson's steel works, in Jersey City, and is ¾ by 2½ inches in the cross section.

First, a piece of Bessemer steel, cut from the end of the bar, was welded fast to itsgrate the heating and welding occupying eight minutes. On the reverse side of the bar a piece of fine cast steel was welded in six minutes. Further along on the bar a piece of blister steel was welded in eight minutes. This same steel cannot be welded with borax, as the high temperature needed with that flux makes it as brittle as cast iron under the hammer. Opposite this a piece of wrought iron was welded in six minutes, and further along on the bar a piece of cast iron was welded in three minutes. The bar was a piece of the mold-board of a plow. The bar, with its additions, was then ground and polished on the edge, so as to show the point at which the welded metal came into contact. No weld was visible on any one of them, and the difference in the metal could only be seen by the color after polishing. This solves great many important problems in iron manufacture, among others the welding of Bessemer steel.

The cause of a leak in the relief light-house New London is found to have been a ham which was probably left in the bottom of the vessel when built, thirteen years ago. Moved with the continual motion of the vessel, it was worn through plank and keel to the copper plating, which alone has kept the vessel from sinking.

SCIENTIFIC PROGRESS.

Fall of a Meteoric Stone—A Large Fragment Secured—Its Structure, Etc.

The fall of a meteoric stone of unusual dimensions was recently reported from Central Iowa. The phenomena occurred on the evening of February 12th, at about half-past 10. Its apparent size, as reported by observers nearby, was about half the diameter of the moon, and accompanied by a beautiful train. The color and vividness were about like that of molten iron. While in view they were seen to separate into many fragments, and after about three minutes the reports of three explosions were distinctly heard.

Visit of a Scientist to the Spot.

Attracted by these remarkable reports Prof. N. R. Leonard, Professor of Astronomy at the Iowa State University, has visited the locality, and has made substantially the following report to the *Davenport Gazette*:

The exact locality of its fall was the south-east quarter of section 5, township 80, range 9 west. It was on the farm of Mr. Sberlock. Some members of his family were returning from a spelling school at the time of the descent of the meteor, and saw, as they thought, three or four fragments fall in the direction of their house. Those of the family who remained at home, heard this fragment as it went whizzing by, and thought that it had passed over the house. They sought for it the next day and the day following, but in consequence of the deep snow, did not find it until Monday, when a daughter of Mr. S. found it about 50 rods northeast of their house.

The meteor struck upon the snow and ice just beyond a little slough that runs through Mr. Sberlock's pasture field, making a very slight indentation in the ground, and bounded northwest a distance of thirty feet or more, up a slight declivity, and came to rest upon the snow. It was apparently warm when it fell, for when found it was adherent to the ice and snow underneath, so that it required a smart rap to loosen it. The professor entertains the suspicion that the place pointed out is not the first place of striking, but that when the snow goes off he shall be able to find on the other side of the slough a more decided mark of impression where it first alighted, and from which it bounded to the spot first mentioned. This, of course, is mere conjecture, but it seems that the impression made upon the ground where it first alighted should have been more decided. The weight of the entire fragment was seven pounds six ounces, though we are sorry to state that before Prof. L. could gain possession of it it had reduced to three pounds eight ounces, to supply specimens, not to meads of science but simply to neighbors or curiosity hunters. This mutilation of the specimen is greatly to be regretted, and as it is every way probable that with the melting of the snow other fragments now buried in the deep snowdrifts will be found, the hope is entertained that the press and all who desire the advancement of science in this rare and deeply interesting field will use all their influence to prevent the mutilation of each other fragments as may be found, and to urge that preparatory to the dividing up of the meteor, among the different museums or cabinets of the State it shall all be collected at one place so that it may be examined and photographed as a whole—or as nearly so as possible.

The specific gravity of the specimen appears to be near 3.50, its structure strong, with some admixture of iron. That face of the fragment which formed a part of the surface of the original body is covered with a comparatively thick black coating, not perfectly smooth; while that face by which the fragment was joined to the main body is coated in like manner, but in a less degree.

The outer surface has the pitted appearance characteristic of such bodies.

Prof. Leonard has placed a sample in the hands of Prof. Hinrichs for chemical analysis, and hopes soon to be able to announce definitely as to the number and proportion of the different elements it contains.

TO SHOW THE PATH OF AN ELECTRIC DISCHARGE.—A correspondent of the *English Mechanic* says: "Take a sheet of glass, wash it well with soda and water, dry it with an unsoaped towel, polish well with a clean wash-leather. Having found the 'striking distance' of your Leyden jar, battery, or electric machine, place the sheet of glass just below the points of discharge, so that they may rest upon it. The shock may now be passed over the sheet, when on removing the glass, and breathing on it, a picture of the track of the electric fluid will be distinctly visible, as clear glass on a dull ground."

THE AGASSIZ MUSEUM.—It is thought that the Agassiz Museum at Harvard, will soon reach the desired amount of 200,000, thus making it possible to draw the \$50,000 appropriated by Massachusetts. With this \$250,000 new halls are to be built, new facilities for instruction are to be provided, and the classification and arrangement of the museum is to be carried forward much further than it was at Agassiz's death.

The Earth—Its Heat and Contraction.

Professor P. M. Duncan, F. R. S., recently delivered at the Royal Institution a course of lectures upon "The Grand Phenomena of Physical Geography." He pointed out that there is strong evidence that the earth is a solid body now cooling. As it cools the rocks must contract; moreover, those rocks which are rich in silica will not contract so rapidly as cooling as others, consequently herein is a source of change of shape of the earth. It is well known that surface changes are going on; that some large areas of land are in course of slow upheaval, while others are slowly sinking, and that at one geological period there was a great upheaval of the larger portion of the continent of North America. The globe, therefore, is cooling unequally. The radiation from some parts is greater than at others, so in this there is a further source of disturbance.

Sir William Thomson has calculated that every year 92 horse power of work—for heat means work—is got rid of from every 247 acres of the surface of the globe. The dissipation of energy and the contraction of rocks not being uniform, the effect of these disturbing causes is to produce horizontal thrusts, which form mountain ranges by crumpling up the earth, for mountains are formed by this crumpling, and not usually by direct volcanic or other upheaval. The changes produced by the contraction are slow, and there is every reason to believe that our present sea floors and our present continents are extremely old, geographically speaking, so far as their present forms are concerned. He said that the upper part of Snowdon consists of sea sand, fossil sea fishes, and volcanic ashes all mixed together; in fact it appears to have been at one time in the same condition that the Bay of Naples is in at present, that is to say, volcanic ashes fell into it and sometimes buried fish. The lower part of Snowdon consists of vast streams of old lava. At some geological period the crumpling action already mentioned took place below the Bay of Snowdon; consequently the bottom of the bay was elevated and became the top of the highest mountain in Wales. Rain, and rivers, and atmospheric changes then played upon it and during the course of long ages, sculpturing out the beautiful mountain scenery which characterizes the Snowdon range.

Structure of Coal.

By close investigation E. W. Binney, F. R. S., believes he has established the following facts: Soft caking, or cherry coal, is chiefly composed of the bark, cellular tissue, and vascular cylinders of coal plants with some macrospores and microspores. Caking coal has much the same composition, except that it contains a greater proportion of hark. Splint, or hard coal, has nearly a similar composition, but with a great excess of macrospores. Cannel coal, especially that yielding a brown streak, is formed of the remains of different portions of plants which had long been macerated in water; it contains a great excess of microspores. Macrospores are from 1.20th to 1.25th of an inch in diameter, and can be easily seen by the naked eye. Their exterior is composed of a brown coriaceous substance, containing within it carbonate of lime, or bisulphide of iron, according to the nature of the matrix. The microspores are about 320 times less in size, and contain some form of hydrocarbon, which, by the action of heat, becomes paraffin. These conclusions were arrived at merely as to the composition of the different kinds of coal. Each seam is materially affected by the nature of the roof, since, if it is an open sandstone, gaseous matter can freely escape, which is, of course, the case when the seam is roofed in with air tight, or shale or blue bind.

The Lower and the Higher Life.

An eloquent inaugural address was delivered by Dr. William Stokes at the late annual meeting of the Royal Irish Academy. After review the recent progress of science, he concluded as follows:

"The conservatism of energy, directive though not creative, in the living organized structure, and the chemical affinities in which that is unorganized, show, it might be held, that a lower mode of life pervades every existing being; but we believe that in God's own time that higher life which shows itself in progressive organization, and is terminable, will have a different existence, at least as regards the human being—one freed from material associations, freed from physical influences and from moral shortcomings. It is believed by thoughtful men that matter is indestructible. May we not find that as it has, in time, subverted the physical, so in eternity, it will, when spiritualized, subvert the moral law, and thus an undying result will be evolved? It has been written that we 'see through a glass, darkly,' but are there not grounds for the belief that each will not forever be the case? May we not believe that every discovery in development, in structure, in chemical composition, and in electrical and optical character, will be, when related to the property of life, a fuller ray of the burning luster by which we approach the footstool of that throne where we shall be permitted nearer and nearer to contemplate the power and the ineffable light of Him from whom comes all life?"

MECHANICAL PROGRESS.

Bearings.

The results of experiments made on the effects of friction between various substances, have recently been tabulated by M. C. Kunzel. The heat produced, other conditions being equal, is in proportion to the hardness of the substances, and, on the other hand the greater the difference in the hardness of two substances rubbing against each other, the less the heat produced by the friction, and the harder of the two heats more than the other. If friction takes place between glass and cork, the amount of heat received by the two respectively is as seven to one, and between bronze and cork, four to one.

For durability alone, of course, bearings should be of metal as hard as that of the arbors which they support, but considering the wear of the latter, the former should be as soft as possible. In practice, however, certain precautions are to be observed; the bearing must not cut the arbor, and it must wear as little as possible; it should not get hot even when lubrication fails, and lastly, it should possess resistance enough to bear all the shocks that fall upon it without being deformed or broken. The alloys of copper and tin generally in use are rarely homogeneous, with the exception of that which contains eighty-two to eighty-three parts of copper to seventeen or eighteen of tin. When there is less tin in the composition, granulation takes place during cooling, which alters the homogeneity of the alloy, and causes the cutting both of bearing and arbor. When an alloy of copper and tin sets slowly, the first part consolidated is a very soft alloy, not containing more than 7 to 10 per cent. of tin; this forms, as it were, the shell of the bearing, while the hard alloys containing seventeen to eighteen parts of tin, sets afterwards and fills up the shell. When a bearing thus formed is in work, the soft alloy soon gives way, and the hard grains within attack the arbor and are often torn out and carried away when grease fails.

A good bearing should be the very opposite of the above; its shell should be very hard and durable, and the interior filled up with a softer composition. This result is attempted to be obtained by fusing together several alloys of different compositions and degrees of fusibility, so as to produce by cooling to given alloys, but the operation is delicate and the result uncertain. Phosphorus bronze succeeds best in this way; the shell is then almost entirely formed of very hard bronze, and the interior of a soft alloy of copper and tin. The bearing may then be considered as a series of layers of soft metal enclosed in a casting of metal almost as hard as the arbor itself. The microscope reveals this disposition with great clearness.

The results obtained with various kinds of bearings used on the Belgian and German railways are thus given: Bronze composed of 83 parts of copper and 17 of tin, costs 3 fr. 25 c. per kilogramme, and wears at the rate of 11.6 grammes for four bearings per 1,000 kilometres, the cost being 0.037 fr.; bronze containing 32 parts of copper and 18 of tin costs 0.032 fr.; the same applied to carriages with brakes, wears at the rate of 109.5 grammes, and costs 0.335 fr.; white metal, composed of 3 parts of copper, 90 of tin, and seven of antimony, costs 3 fr. 73 c., wears at the rate of 14.8 grammes, and costs of 0.055 fr.; ditto containing copper 5, tin 85, and antimony 10 parts, costs 3 fr. 66 c., wears at the rate of 11.3 grammes, and costs 0.041 fr.; ditto composed of lead 84, and antimony 16 parts, costs 1 fr. 48 c., wears at the rate of 12.2 grammes, and the expense is 0.018 fr. per 1,000 kilometres; lastly, phosphorus bronze costs 4 fr. 37 c., wears at the rate of 2.3 grammes, and the expense is 0.010 fr. only, but when applied to carriages with brakes, the wear rises to 9.5 grammes, and the expense to 0.041 fr.—Iron.

NEW AND VALUABLE PRINTING PRESS.—A new printing press made in Liverpool, Eng., by Dunan & Wilson, for the *Christian Union* newspaper of New York, is a remarkable novelty in this class of mechanism. It prints, folds, pastes, and binds the paper inside of a cover, which it also prints; and delivers the numbers, thus completed, at the rate of 5,000 copies per hour, and may be worked up to 6,000 per hour. The paper is drawn from a roll. The whole machine is 27 feet long, 7 feet high, and the cost is \$20,000. The folding apparatus may be disconnected whenever necessary, and the machine used to print without folding. Various attempts have heretofore been made to attach folding machines to printing presses; but this, we believe, is the first successful example of the kind.

IMPORTANT DISCOVERY.—It was an accidental discovery by Goodyear that brimstone would vulcanize India-rubber, and one of the most important to the industrial interests of the world. An accidental discovery of recent date, it is said, makes it possible to enamel cast-iron, and all kinds of bearings, and thereby prevent the friction and heat which is so expensive, dangerous and often disastrous in running cars and machinery. Des Moines capitalists are getting ready to introduce the article. It can be applied like a lubricant, and just as readily.

Toughened Glass.

We have made several allusions to the late French improvement in glass manufacture, whereby that heretofore fragile material is made to possess a good degree of toughness; but we have not, until the past week, been able to learn the means by which this toughening is accomplished. This process appears to be distinctly announced in the following paragraphs, which recently appeared in the *London Times*:

It has long been known that when glass is heated to redness, and kept at that temperature for a considerable time, its physical properties are changed in a remarkable manner. Thus it becomes opaque or feebly translucent, much harder and tougher, and somewhat like porcelain in appearance. This change is termed "devitrification," and is caused by the conversion of the glass into a coarsely-crystalline mass, of which sections are beautiful objects when seen with a microscope in polarized light. The subject was investigated by the renowned French philosopher, Raman, early in the last century; and to objects of devitrified glass the name of Raman's porcelain is usually applied. Such objects are exhibited in the Museum of Practical Geology, in Jernyn street, London.

It has been reserved for another Frenchman, a gentleman farmer, to discover the singular fact that when glass is heated to redness and then cooled or annealed in oil its toughness is greatly increased, or, what is equivalent, its fragility is greatly diminished, while its transparency remains the same. Thus, suppose a rectangular pane of glass placed flatwise and supported on two of its opposite edges to break when a given weight is allowed to fall upon it—say, from the height of two feet—it would, after having been toughened in the manner above stated, resist the same weight falling upon it from the height of six feet or eight feet. It is strange that, although glass has been manufactured during the last 2,000 years, yet such a simple and probably very important fact as this should only recently have been found out, and equally strange that the discoverer should be a gentleman farmer.

The foregoing information on the new process of toughening glass is given on the authority of Mr. C. W. Siemens, F. R. S., who is well known in connection with telegraphy and the furnace which bears his name. His brother, an eminent glass-maker at Dresden, has tried the process and pronounces it to be "certain and unquestionable."

ALLEGED IMPROVEMENT IN SHOT GUNS.—Capt. John L. Kerr, of Allegheny City, and Wm. D. Squires, of Sioux City, Iowa, have recently received Letters Patent for an improvement in shot guns, which it is said, promises the greatest utility to sportsmen. It consists simply in a parallel enlargement of the bore of the gun at the muzzle some seven or eight inches down. For the last month they have been making the most minute tests, and have reduced the improvement to fixed rules, by which any good gunsmith can make a correct shooting shot gun, or improve almost any gun now in use. Their principal tests were made with old Harper's Ferry muskets, and notwithstanding their ponderous, non-elastic character, they were made to shoot as well or better than the best imported shot guns.

If such is the fact, that an old musket, with so trifling an expense, can be made to shoot as good if not better than the best imported English guns, the invention is most certainly an important one.

A VALUABLE metallurgical process has recently been brought forward by a Birmingham inventor, which admits of the filing of articles of brass with molten iron. The balance weights for chandeliers, pillars, columns, and large weights may be made, advantage being taken of this process, at a much diminished cost. It is simply necessary to immerse the brass shells in water, and the molten iron is then poured in. The shell cannot, of course, attain a higher temperature than 212 degrees, the boiling point of water, while the temperature of its contents may be about 3,000 degrees. In making large or imperial weights by this process, the plan devised by the inventor is that of imbedding the shells in iron filings, the high conducting powers of which is thus turned to account.

CANAL STEAMBOATS.—According to the recent report of the State Engineer of New York, the steamers on the Erie canal, invented by Mr. Baxter, have successfully solved the problem of rapid transit, so far as canal navigation goes. Nine steamers of the Baxter Company were in operation on the Erie canal last summer, and this fleet will be increased the coming season to one hundred. The average time of their round trips from Buffalo to New York has been fifteen days, consuming only twelve tons of coal during the round trip.

TUNGSTEN STEEL.—A simple and certain process, it is claimed, has been perfected by Biermann, of Hanover, by which a white, exceedingly hard and brittle cast-iron, containing from five to forty per cent. of tungsten, can be produced, which is adapted to chilled work, and can be added to cast-iron in any proportions.

Mining Stocks.

The mining share market has been pretty lively this week, and prices realized have been good. The Gold Hill end of the Comstock has been in the ascendant, and transactions in these stocks have been comparatively extensive. Movements in Idaho and Ely district stocks have been small, the principal attention being drawn to Comstock mines. Of the situation there the *Enterprise* thinks that, eventually, the improvements and new developments now steadily being made along the line will attain such importance through constant accumulation that they will force recognition in the market. Although the impetuosity of the people at large constantly runs far ahead of drifts, cross-cuts, winzes and all other works undertaken for the development of the Comstock mines, yet all these openings are being pushed toward the great ore-bodies as rapidly as men and machinery, working day and night, can perform the task. When the public mind has become excited and has run too far ahead of the reality, it has nothing to do but to return, take a rest and start again when the humor returns; meanwhile the real work in the mine is steadily, though it may be slowly, advancing.

The *Enterprise* says: All is going on well at the north end of the lead, and in due season there will no doubt be new and valuable developments to report, which will gratify and satisfy the clamoring and excitement-loving surface world for at least three days. It is not only at the north end of the lead that prospecting operations are tedious, but also at the south end, and in all other places where hard rock is to be passed through and floods of water, deficient ventilation and other obstacles to progress are to be overcome. All is being done in all of our mines that men and machinery can do, and we shall see many valuable developments along the Comstock before many months have passed. Toward the south end of the lead two or three companies are upon the eve of opening up bodies of ore, and ere long we may expect to hear good news from some of these. Several "outside" mines are already furnishing ores to the mill for reduction, and very soon some others will be doing the same. Our prospecting companies are all in excellent spirits and the people generally have unbounded faith in the permanence and value of the mines along the Comstock range.

JUDGING from reports from the Nevada county papers it seems that many new claims are being started up and that prospectors are not idle. The *Foothill Times* says: We want a score or more mines of the class of the Idaho, Empire, Enreka and New York Hill at work, in order to make things prosperous as Grase Valley deserves to be, and the only way left to bring about such a result, since capital seems attracted to California street operations on the Comstock, is for miners themselves to go to work and show that their properties are really valuable; when, after the re-creation from stock-gambling takes place, as it surely will, men of means will be glad to invest in and properly open them.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

PLUTO P. F. Co., March 27.—Object: Buying, selling, and operating quicksilver furnaces in the States and Territories of the Pacific coast. Capital stock, \$150,000. Directors—H. H. Eames, R. D. Walbridge, Wm. L. Ward, Matthew Bridge, and John W. Fitch.

FRANK PATTERSON G. M. Co., March 21.—Capital stock, \$2,000,000. Location: Indian valley, Plumas county. Directors—H. C. Bidwell, H. Cox, Thomas J. Kerr, Paul Cornell and Miguel J. Quin.

PACIFIC ECONOMIC M. Co., March 27.—Object: To work the Moose mine, in Utah Territory, and to mine in California and Nevada, and the States and Territories adjoining the same, and to carry on mining and prospecting works and machinery, and to establish agencies in New York or elsewhere with a view to procure funds for the corporation and to act as agents of mining companies, owners of mines, or others. Directors—James Brodie, William H. Cummings, Alexander Kydd, A. H. Griffith and S. Strahan. Capital stock, \$5,000,000.

CORONADO CONS. G. AND S. M. Co., March 29.—Location: Elko county, Nevada. Directors—J. B. Fitch, J. W. Pence, L. I. Mowry, Edward Chatlin, and Mrs. M. Pierson. Capital stock, \$10,000,000, divided into 100,000 shares.

CONS. ALABAMA G. AND S. M. Co., March 30.—Location: State of California. Directors—Michael McDonald, Wm. W. Burns, W. L. Higgins, Augustus Laver and Edward A. Edwards. Capital stock, \$7,500,000, divided into 75,000 shares.

WEST END D. TILLING Co., March 30.—Capital stock, \$300,000. Object: Manufacturing spirits in this city and county. Directors—J. G. Goldsmith, A. G. Van Winkle, J. B. Snyder, Thos. Donnelly, and J. H. Scrubridge.

AUBURN GRAVEL M. AND DITCH Co., March 30.—Object: To conduct the general business of mining and conveying water in Placer and Sacramento counties, and elsewhere in this State; to construct all works necessary for the proper extraction and reduction of ore and metals, and the conveying of water; to acquire mineral mining claims, mill sites, water rights, ditches and flumes, and other property pertaining to the general business of mining and conveying water, and to hold, use, and dispose of the same. Directors—P. Crowley, James Gannon, C. N. Felton, H. F. A. Schussler and William T. Higgins. Capital stock, \$1,000,000, divided into 10,000 shares.

BADGER CONS. M. Co., March 30.—Location: Goose Creek district, Elko county, Nevada. Capital stock, \$8,000,000, in 80,000 shares. Directors—Jas. A. Pritchard, E. W. Leonard, D. Porter, Matthew Canavan and Joseph McGillivray.

TERRACE CONS. M. Co., March 30.—Location: Goose Creek district, Elko county, Nevada. Capital stock, \$8,000,000, in 80,000 shares. Directors—J. A. Pritchard, E. W. Leonard, D. Porter, M. Canavan, and Joseph McGillivray.

SCOTIA M. Co., March 30.—Location: Poverty Hill, Sierra county, Cal. Directors—A. T. Elliott, H. Wikeman, David H. Walker, T. F. McCarthy and J. H. Dickinson. Capital stock, \$5,000,000, divided into 50,000 shares.

SANTA CLARA COUNTY M. Co., March 30.—Location: Santa Clara county, Cal. Capital stock, \$2,000,000. Directors—J. Neale, E. J. Wilson, R. B. Harper, John Harper and Henry Michaels.

THIRTY-FIVE trains are now running daily over the Virginia and Truckee railroad.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior in proximity to the mines mentioned.

California.

AMADOR.
RIOB STRIKE IN THE KENNEDY.—Amsdor Ledger, March 27: We are pleased to chronicle the fact, that in sinking the main shaft in the Kennedy mine, a very rich strike has been made at the depth of 700 ft. The ledge at that depth presents a width of 6 ft, and increases as sinking proceeds. The ore now being taken out is evidently the richest, as a body, yet discovered in the mine, the rock being the regular ribbon rock peculiar to the great mother lode, and well charged with free gold and rich sulphurets. The main shaft has evidently reached the south edge of an extensive chimney lying north. The company will, in a short time, commence the erection of a forty stamp mill to be propelled by water, which will be, when completed, a great saving in the cost of crushing over steam power.

THE ST. MARTY'S GRAVEL CLAIMS.—Several days ago there was a partial clean up of a few days run on pay gravel in the above named claims, which revealed the fact that the claims contained very heavy gold; one nugget weighing \$46, and a large number of others varying from \$3 to \$10. The company are now placing three hydraulics on the claims, two Little Giants, and one of less caliber. The claims, which embrace near nine acres, nearly the whole of which is valuable mining ground, belong to the Amador consl and mining company.

RUSSELL HILL.—Mining is being vigorously prosecuted at Russell hill, with very satisfactory results, and preparations are being made to mine the hill on an extensive scale. No doubt exists as to the richness of the ancient channels penetrating the hill, and when the underground system of these channels shall be understood, so that they can readily be followed, heavy returns in gold will be obtained.

BUTTE.
IRON.—Oroville Mercury, March 26: For some time past it has been known that iron existed in considerable quantities over in Wyandotte township, in this county. A few weeks since a party traveling over the hills came upon a rock that seemed to him highly impregnated with the ore. He broke off several pieces and gave them to his friends in town. One of them was sent to an assayer in San Francisco, with the request that he would test it and see what amount of silver and gold there might be in it. The answer returned was that neither of the above metals were to be found, but that it was rich in magnetic iron. Soon after a company was formed, consisting of Thomas Callow, Supervisor Freer, E. A. Mathews, G. M. McBride, A. Goldstein, and a man by the name of Meyers, who lost no time in staking off their claims. It is within seven miles of the railroad, over a good road, part of the way, and the balance can easily be made so. In the immediate vicinity is to be found an abundance of the best kind of lime rock, and also plenty of wood and water.

ate erection of a furnace. A furnace, however, will involve a heavy outlay of money, principally in the construction of roads, and before going into this expense, he deems it best to personally explain the entire situation to his brothers, living near Visalia, who are largely interested, and for this purpose he goes over there next week. Mr. Moffat has been prospecting in the vicinity for fire clay, and has opened some that is thought will do, but which is to be submitted to a furnace test at Cerro Gordo. The prospects are altogether favorable for the immediate construction of a furnace.

NEVADA.

OMAHA MINE.—Grass Valley Union, March 30: This new ten inch pump at the Omaha mine is now safely in the mine, and began its work last Saturday. This pump will be able to fork out the water for a great many months to come, and there can be no danger now of the mine filling up any more. The Omaha's sulphurets, left over after the last crushing of ore, have been worked. Those sulphurets have behaved very well, turned out rich in fact, and gave the neat result of \$116 to the ton. With rock that pays about \$53 to the ton exclusive of sulphurets, and then sulphurets paying \$116 a ton, we call the Omaha ore very good.

PUMPEO OUT.—The shaft of the Idaho is being dipped out. It has been re-timbered for 100 ft, from the 900 to the 800, and while the men were timbering it the water was allowed to collect. A large tub raises the water to the 600-ft level, where the big pumps get at it and raise it to the drain tunnel. It will take several days to get it in "fork." As soon as this is done they will put in the rails and the shaft will be completed and ready for the cages.

GASTON RIDGE MINE.—The Gaston Ridge mine, situated between Washington and Eureka South, in this county, is working along very well. The new tunnel is now in about 400 ft, and in about 70 ft more the ledge will be cut. The ledge is a very large one and as far as it has been worked shows well in the true indications of richness namely: free gold.

DAY MINE.—Foothill Tidings, March 27th: The Day mine, situated in Willow Valley, near Nevada City, which was worked some years ago and produced many thousands in gold from near the surface, but never was opened to a depth of over 30 ft at any point, has recently passed under the management of Capt. T. W. Moore and others, who have purchased steam hoisting machinery and are preparing for an energetic movement thereon. The Day is noted for the great length of pay chutes developed near the surface and for the good average quality of the rock taken out, as it were, from the "grass roots." We are told that the last day's work was done on the ledge at a depth of 30 ft, below which they could not get because of water, and the then owners were not able to put on machinery for pumping, was in ore which would pay sixty dollars per ton, and it is believed that with the facilities for work which are now being put on, this mine will soon make croakers and sleepy-heads open their eyes with surprise.

THE Howard Hill mines, Lucky and Cambridge, now owned by a San Francisco company and working under the superintendence of Captain John White, are likely to soon redeem that once famous locality from the disrepute it has fallen into these last few years. Considerable prospecting has been done the past winter and a few days since the stamps of the Gold Hill mill were dropping on a grist sent down from there. About twenty tons of rock was put through, which yielded, as we understand, at the rate of \$40 per ton. This we believe was from the Cambridge lode about 40 ft deep and the ledge averages at this depth about a foot in thickness. This result will be very apt to induce an increase of force and the starting up of the company's mill.

PLACER

GREENE MINE.—Placer Herald, March 27: With the completion of the new eight-stamp mill, this company have, undoubtedly, the most perfect and convenient works in the district. The buildings on the mine are neat and substantial; the machinery of the most approved kind. The mill, being convenient to the shaft, is driven by the same engine, (40-horse-power) that drives the pump. Another engine, 16-horse power, is used exclusively for hoisting. The water from the mine is raised above the building, whence it is conducted, by pipe back to an immense reservoir in the side hill, from which it is drawn to supply the mill and boilers, as needed. The mine itself is well opened. The main shaft being down about 300 feet, from which two levels are run, one at 100 feet, and the other at 200 feet deep. The first named is in from the shaft about 50 feet east, and about 75 feet west; the second is in from the shaft about 140 feet east, and about 110 feet west. They are now stopping from each side of the main shaft between the 100 ft. and 200-ft. levels. The mill is kept steadily running to crush the rock as fast as it is hoisted from the mine. There has yet been no clean-up since the new mill was started, but indications for fair returns are favorable. The energy displayed by this company is a matter of just praise. Supt. Wm. Green, and Frank Laveley, the competent and accommodating foreman, both shareholders, are entitled to much of the credit.

QUICKSILVER.—A few days ago C. C. Ragdale handed us a piece of ore from the Nickerson quicksilver mine, located a short distance the other side of Bear river, which, from appearances is quite rich. Men working in the mine pronounce the ore worth 5 per cent. in quicksilver. The shaft on the mine is now down about

90 ft. The width of the ledge is not exactly known. From the croppings it is supposed to be at least 200 ft. wide.

SANTA BARBARA.

QUICKSILVER MINES.—Santa Barbara Index, March 29: The news from over the mountains is of the most encouraging character. There are good reasons for believing that the Santa Barbara (Los Prietos) quicksilver mines will prove the richest in the world. The energetic superintendent, Mr. Cassell, is driving the work right ahead, and once his furnaces are in operation, and that will be soon, the world will learn something of the mineral wealth of Santa Barbara county.

SONOMA.

PROSPECTING.—Sonoma Democrat, March 26: Recent explorations near Bunch's Station, on the Healdsburg and Pies Flat road, have proven the existence of gold and silver bearing quartz as well as stone coal. Captain Eastman has located claims of such of those minerals, as well as of quicksilver. The gold and silver mines are the Star and Wandering Jew, and the quicksilver ledge is called the Wanderer.

SISKIYOU.

MORNING STAR.—Yreka Union, March 27: The Morning Star company started up their eight-stamp mill about a week ago, and the plates of the batteries are looking very well. This company experiences more difficulty in saving their gold than any other company on Salmon, owing to their quality containing considerable silver, which latter they have not as yet any means of saving. The prospects of this mine are looking extremely good at present.

As a proof of the immense quantity of quartz in this section, we are informed that Mr. Hobson claims to have knowledge of the locality of no less than 40 different quartz ledges.

BUSINESS at the Ber is looking 'n'p, and the prospects for a prosperous future were never better.

THE Klamath quartz mine under the superintendence of friend Deggett, is coming to the front rank among quartz mines. Each month's clean up shows an increased yield of ballion over the last. This company have lately attached revolving blankets to their batteries, and are now putting up pans, settlers, etc. The company intend shortly to erect a furnace for the purpose of roasting their sulphurets.

THE Star of the West company have now an 8-ft ledge, at about 87 ft below the surface, and the ledge is continually widening. The quartz is very rich, a large percentage of it exhibiting free gold. Some specimens of quartz from this ledge are as rich as we have ever seen come out of any mine.

Messrs. Bennett and Miller have nearly completed their arrangements for working the forks of Salmon Bar. This Bar is very large, and has paid rich all around it, and there is hardly any doubt that there is pay all through it. Messrs. Bennett and Miller are both live and energetic men, and have expended a large amount of capital in this enterprise. We wish them unbounded success.

TUOLUMNE.

CINNABAR.—Tuolumne Democrat, March 27: Some pieces of float cinnabar has been found at Marah's flat, on the south side of Tuolumne river. Several parties have taken up claims and are now hunting to find the vein; they have much confidence in being successful. A small piece brought from there we have seen; it is rich in quicksilver.

TULARE.

GOLD.—Tulare Times, March 27: From a reliable source we learn that gold has been discovered in the foothills, near Wag's mill, and about 35 miles from Visalia. Some parties are now engaged in washing on a small scale, but profitably successful. Further prospecting may result in some very rich discoveries. Our mountains have never been thoroughly prospected and wonders may yet be discovered.

Nevada.

WASHOE DISTRICT.

SERRA NEVADA.—Gold Hill News, March 25th: Sinking the new shaft is making excellent headway. The water no longer interferes with the work. Driving the northeast drift on the 700-ft level of the old shaft is making good progress, the face in ledge matter.

LEO.—The northeast drift, running from the north cross-cut, is now in 25 ft, and the vein of ore in the face of the drift is from 15 to 18 inches wide, and still widening. The ledge at this point is about 40 ft wide, and the prospects of making a good development are steadily improving.

JUSTICE.—Main drift south at the 800-ft level now in 55 ft from the incline, with the face in hard ledge matter and very wet.

LARRY BAYAN.—Driving the southwest cross-cut on the 380-ft level is going steadily forward, with evident indications of soon reaching the ore vein.

KOSUTH.—The main west drift on the 350-ft level has penetrated the ore vein a distance of 70 ft, proving it much more solid and hotter defined than on the levels above.

WELLS-FAIGO.—The sinking of the new shaft is being pushed forward as lively as three shifts of men, working night and day, can do it.

DAYTON.—Sinking the main shaft below the 400-ft level is still making good progress. The face of the main south drift on the 300-ft level is still in a fine character of quartz and low grade ore.

LARRY WASHINGTON.—Shaft down over 400 ft. Two ft per day are made at present. The water has decreased somewhat, being probably drained to a certain extent by the Justice shaft.

SILVER HILL.—The north prospecting drift, on the third station level, is showing much more favorable indications of an ore development in that portion of the mine.

EUROPA.—The face of this drift or cross-cut, from the winze, 113 ft below the adit level, is now through the west wall of the ledge and cutting into the vein itself, the whole face being in quartz, which looks splendidly and gives good assays.

AMERICAN FLAT.—The main south drifts on both the 750 and 800-ft levels are still driven vigorously ahead, running nearly parallel with the ore vein, and affording some very promising indications of good ore developments ahead.

ORIGINAL GOLD HILL.—The cross-cut from the main south drift, to intersect the valuable ore development found in the npraise above that level is about cutting into it.

SAVAGE.—The main south drift on the 2200-ft level has not yet completed a connection with the north drift from the bottom of the south winze, but will probably do so in a day or two more. When that is accomplished, the drifts enlarged to a good working size, and car tracks have been laid, the cross-cutting of this level can be commenced, and some good results may be looked for.

CALIFORNIA.—Sinking the O & C shaft is making splendid progress. It is now down 300 ft. The re-timbering of the north drift on the 1550-ft level is making steady progress. The face of cross-cut No. 3, on the 1500-ft level has encountered ore of a very rich character, proving more and more the steady continuation of the ore body to the northward. The north drift on the 1500-ft level, to connect cross-cuts Nos. 2 and 3, is still in ore of the finest possible description. East cross-cut No. 2 encountered a few small clay seams during the fore part of the week, which have again given place to fine solid ore. The winze being sunk from east cross-cut No. 2, on the 1400-ft level, to connect with the north drift on the 1500-ft level, is down 38 ft, the bottom still in fair grade ore. The south drift on the 1400 ft level, from this winze, to connect with east cross-cut No. 1, is in 97 ft, the face still in low grade ore.

OPERA.—Daily yield, 150 tons of ore. There is little or no change to report of either the yield or appearance of the ore breasts on the 1465-ft level. Sinking the northeast winze below the 1465-ft level is making good headway, following the dip of the ore, which at that point inclines to the north and west. The northeast drift on the 1600-ft level at the bottom of the north winze is still driven vigorously ahead, the face still in rich ore. This drift is in a distance of 60 ft, all the way in good ore, and insures the development of a valuable ore deposit on that level. The southwest drift at the 1600-ft station of the new shaft is making good headway, the face still in hard porphyry.

CONSOLIDATED VIRGINIA.—There is no prospecting being done in the mine at present, with the exception of running the east cross-cut on the 1400-ft level, on the California line. That drift is in a distance of 165 ft, the face still in porphyry, with occasionally small stringers of quartz. This drift has probably 30 or 40 ft yet to run to reach the ore vein. The mills are all running steadily and everything in and about the mine looks bright and prosperous.

OVERMAN.—The heavy flow of water in the main shaft is kept below the 900-ft level by active pumping. Preparations are being made to put in the new pump, which is contracted for and will soon arrive.

CROWN POINT.—Daily yield, 500 tons of ore, keeping the company's mills steadily running. The ore breasts on the 1400, and those between the 1400 and 1500 ft levels, are all looking well and yielding the usual amount of milling ore. Cross-cutting and prospecting on the 1600-ft level is still energetically carried on, without any valuable developments to report. The 1700-ft station is about completed.

NORTH CONSOLIDATED VIRGINIA.—The new shaft of this company is located 2000 ft north of the great C & C shaft, Virginia, and is now down 85 ft. It consists of three compartments, substantially timbered, and is sinking in very promising vein material, some of the quartz assaying from \$3 to \$8 per ton.

UTAH.—The erection of the new pumping machinery is making steady headway. Prospecting the ore vein both north and south on the 400-ft level is still vigorously prosecuted.

SENATOR.—The southeast cross-cut on the 400-ft level is showing a steady improvement as the drift advances into deeper ground. The ore in this drift has from its commencement shown much base metal, which could not be worked by the ordinary milling process, but there is every indication now of the ore becoming more free as the drift advances.

GLOUCE CONSOLIDATED.—The face of the main west drift on the 400-ft level is still in quartz and ore of a fine character.

MEXICAN.—The ore in the face of the north drift on the 1465-ft level is looking much more promising as the work advances.

CALEDONIA.—The incline shaft is timbered and finished to a depth of 60 ft below the 1000-ft station. Prospecting on the 900 and 1076-ft levels has developed nothing new during the week.

FLORNA.—New shaft down 446 ft to-day. The foundations for the new boilers and heavy hoisting machinery are being laid, and all the arrangements for the new works are being laid out and directed under the supervision of Mr.

Patten, the constructing engineer of the new mill and works of the Consolidated Virginia mining company.

GOUTIN & CUREY.—Driving north on the 1700-ft level, to connect with the south drift from the Best & Belcher, is making steady progress, the face continuing hard blasting.

CHOLLAR-PORTER.—The face of both the south drifts on the 1150 and 1250-ft levels are still in barren porphyry. Grading the site for the company's shaft is making steady progress.

JULIA.—The main south drift on the 1000-ft level is still pushed vigorously ahead, the face in soft porphyry with a mixture of quartz and clay of a very favorable character.

ROCK ISLAND.—The shaft is down 231 ft below the first station level, the bottom in good working ground. It is the intention to open a new level at a depth of 20 ft more, and start a drift for the ledge.

KNICKERBOCKER.—The north and south drifts on the 600 and 700-ft levels are still driven energetically ahead, following the east clay wall of the ledge.

NIAORA.—Sinking the incline shaft: has been resumed. This shaft is down a depth of 150 ft, at which point ore of a high grade was encountered. Some fine developments are confidently looked for as greater depth is attained.

SUTRO.—Excellent progress is being made with the main west tunnel, the face still in soft working ground. A considerable flow of water will probably be encountered before the main ore vein is reached.

LEVIATHAN.—Shaft down 150 ft. Some spots of very good ore are occasionally met with, and the prospects for developing a good, paying mine are excellent.

IMPERIAL-EMPRE.—Sinking the main incline is making fair headway. The main south drift and the east cross-cut on the 2000-ft level are each still driven vigorously ahead.

YELLOW JACKET.—Cross-cutting the ore vein, on the 1740-ft levels, is being pushed vigorously ahead, with some favorable ore indications, but nothing that as yet indicates paying bodies of ore.

WOONVILLE.—Sinking the winze in the north drift, below the 300-ft level, is also making good progress, the bottom still in ore of a fine character.

Oregon.

THE MINES.—Walla Walla Union, March 20: Until quite recently the prospect for a good mining season has been very dull indeed, for although we have had unusually heavy snows in the valleys it was unusually light in the mountains, consequently there was no prospect of a good supply of water. But within the last week or two there has been a considerable addition to the amount of snow in the mountains, and the prospects for a moderate supply are greatly increased thereby. Still there will have to be a good deal more fall before a good and abundant supply will be assured.

MARYSVILLE MINING & WATER CO.—Bedrock Democrat, March 24: On yesterday we had the pleasure to make the acquaintance of Mr. Best, who has just arrived from Marysville to attend to the interests of the Marysville water and mining company, whose works are located at Auburn, in this county, where they now have in 1,500 ft of flume, which will convey some 2,000 inches of water. It is the intention of the superintendent to run day and night and it is expected that they will be able to wash down 1,500 square yards of ground every 12 hours. The company are well pleased with their prospects, and look for big pay from their mining operations this season. Mr. Best has the appearance of being a practical man, and understands the business of which he has charge. The company have five goose neck nozzles from 2 1/2 to 3 1/2 inch, and three Little Giants on the way here, some of which will be for sale. Here will be a good opportunity for some of our hydraulic companies to supply themselves with these improved means of washing down banks. The Marysville company will commence running as soon as water starts.

Arizona.

LOCAL MINING AFFAIRS.—Arizona Citizen, March 20: It is now fully demonstrated that the Ostrich lode is at least six miles in length, and runs from five to ten feet in width. The new discovery made by D. C. Thompson, three miles from the Ostrich, is simply that distance from the Ostrich mine but on the same lode. Tom Roddick, who was among the first discoverers and is now an enthusiastic explorer of the country, says that he is convinced that the Ostrich has the full extent of length, thickness and richness that anybody has ever represented. In opening up the Sultan and Crescent, fully three miles from the Ostrich claim, he finds the vein ten feet wide. He is making a cut across the top of about twenty feet from which a shaft is to be sunk. He was in town early in the week for supplies, and while here had two assays made from the top ore; one showing it to contain \$9.42 in silver and \$120.58 in gold, and the other \$9.42 silver and \$75.36 gold. From the Eclipse claim, he had one sample assayed which gives \$61.26 silver and \$60.29 gold. This is the lowest in value of any sample we have heard of being made, and assays have been made of ores taken from various parts of the lode for six miles.

A man whose name we did not learn, came in this week with a pound and a quarter of gold taken from ore reduced in an arrastra off southward. The gold was put into a bar at the Tucson assay office.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Ninth Lecture Delivered before the University of California College of Agriculture, on Friday, January 29th, by PROF. C. E. BESSEY.

Insectivorous Plants.

A week ago I called your attention to some peculiar things, certain peculiar relations existing between plants and insects. Now, strange as these relations, existing between plants and insects may seem, there are others stranger still. If it is a strange thing that insects in visiting certain plants in search of honey must pass into the flower by one channel and out by another, or, if the slight motion imparted to the stamens excites our wonder, what shall we say of the plants which have paths dotted with nectar to lure honey-loving insects, or those with traps set for their prey, which, when caught, they afterwards digest; or those still stranger ones which actually reach out and seize the unfortunate insect that ventures too near and hold it in an embrace which only ends in the total destruction of the victim? Such plants, the ones of which I shall speak this afternoon, may very properly be called insectivorous (insect-eating).

There are the Pitcher plant, Sun Dew, Fly-trap and a few others, and we have here before you illustrations of them.

The Fly-trap is represented here, [Fig. 1.] There are several species of the genus *Sarracenia*, and this genus is well represented by these two diagrams; this found in the Northern States, and this found in the Southern States. [For a representation of one species, see Fig. 2.] Several species of this genus have, as you know, leaves which are pitcher-shaped, or in some cases trumpet-shaped. You see the upper one bears some faint resemblance to a pitcher. These are allied to it. [The Professor here pointed to sketches illustrating different plants, pointing out some of their peculiarities.]

These leaves have more or less water in them, or, a watery fluid.

This fluid is secreted at certain times—

Not at all Times—

Sometimes there is no fluid.

At other times you find an abundance of it. It is found upon chemical tests to have a decided re-action. If any meat or organic matter is put into this fluid, it will act as a solvent. Bits of flesh allowed to remain in it for a time will be found to have dissolved much more rapidly than if they had been placed in ordinary water.

This fluid, instead of being rained in, as it might seem, seems to be actually secreted. That is, there are little glands placed along from this point downwards. These little glands secrete this fluid and pour it out. [The lecturer then spoke of certain peculiar arrangements in the habits and structure of these plants, showing that this fluid certainly is a secretion, and is not rained into the receptacle containing it.] Above this surface, which is found in these tubes, the inner walls are made exceedingly smooth, and above this smooth track is another, covered over with bristles, which are pointing downward, and so arranged that as an insect visiting the flower gets upon this it loses its foothold very readily.

So you see how it would act. Supposing an insect happens to get into this water here and tries to get out; it first has to cross this smooth track, and if it succeeds, above that then it meets this array of bristles. The edge of these bristles is so smooth it cannot get any hold at all, as there seems to be a *cheval de frise* of the cavity. Around the mouth is a

Track Covered With Honey,

And this is secreted in some species in very great abundance. And more than this, there is a little pathway of honey right around this point [refers to diagram], and upon this lid-like portion there are little drops of honey, and then along this to this part right here.

These honey drops are placed along so that insects are attracted by this. They follow it up just the same as a pig follows up a trail of corn. The insect passes just over the edge of the leaf, plunges down and over it, goes into the bath below, and, from experiment, it is found they can never get out.

Now this watery fluid into which the insect falls has an acid reaction, and is somewhat allied to the gastric juice of the stomach, so that it actually digests these insects. This fact of the arrangement of this honey pathway for luring the insect to the top of the leaf and then having it fall into the fluid secretion was just made out within the last year by certain physicians in the Southern States.

This is the *Darlingtonia Californica*. [Fig. 3.] It differs from this order of pitcher plants in this; that while in this case [Fig. 2.] the upper part of the leaf is more or less open and exposed to the air, in this, [Fig. 3.], the open point is away under this edge, and from the edge of this opening there is hanging down a very strange appendage, which has a red color; and, by the way, I should call your attention to the fact that we have some brilliant colors placed up here close to where the lure is given. A portion of the plant is

Smear'd Over,

To use an observer's own expression, with honey. Now, see how the insects act. Insects usually visit the flowers which have some

bright color or which have some strong odor, some fragrance; those are the things which usually attract them. The insect, flying along, notices this, and is lured on until very soon it is toppling over into this water in here, where it is imprisoned and very soon is digested.

Now another thing pointed out by an observer is this: This appendage is found to have about the same color as the plant itself, and he makes this suggestion that it would be well to notice whether the plant has not attempted here to feed these insects in one case and in the other case to feed upon them; whether those of

Fly Traps. As to the use made of the captured insects, it would appear from the observations made within the last year that it is altogether likely, perhaps quite certain, that the plants make use of this decaying matter in just the same way animals make use of the food received which is in their own stomachs; so that these are so far like animals.

Drosera, or Sun Dew, is one of the small marsh plants. Its leaves are covered over with little viscid, glandular hairs. If a piece of organic matter such as an insect or piece of beef be dropped upon one of these little leaves,

Fig. 3—DARLINGTONIA CALIFORNICA.

the very same color, which in one case would give the insect honey and pollen and everything that it wants, in the other case following it up carefully—will not be found to lure it on till it flies over into this cavity and is destroyed. Some hold that in this case, as in this other, there are smooth tracks, perfectly smooth, so that the insect can readily pass out and that others are covered over again with retrorse prickles so that when an insect is once in there it stays there, and never can get out. In an

the hairs very soon begin to turn toward this bit of beef. Very soon they touch it with their little glandular tips, and when one touches it sticks. Very soon the leaf folds over the insect and actually in a short time it coils around so that thirty, forty, or fifty of these little hairs

Fig. 1—Two Leaves of the Fly Trap.

allied form, but in a near relative, the

Pitcher Plant

Of the East having very near the same arrangement. This is the plant found in the Eastern Hemisphere. It climbs by these tendrils. This plant has been known a great many years, simply as a curious one. You find it spoken of in all your botanies as an example of what a plant can do in modifying its original leaf form. Dr. Hooker thinks this has also a leaf track as there is more or less honey also upon this. There is also found abundance of water in here which has the same chemical characteristics, so that it actually works the same way the *Darlingtonia* does. This is a species of *Sarracenia*. These are known as the Pitcher Plant

Fig. 2 *Sarracenia Drummondii*.

close around the insect; of course the insect is destroyed.

Mrs. Mary Treat, an observer in New Jersey made the following observations:—

At fifteen minutes past ten she placed a piece of raw beef upon a leaf of one of her plants and at ten minutes past twelve,—that is just about two hours—two leaves had folded over the beef, partially or entirely hiding it from sight.

At 11:30, the same day, she placed living flies upon leaves of the plants, and at 12:48—a

little more than an hour afterwards—one of the leaves had folded

Entirely Around its Victim,

And some time after the fly had ceased to struggle. At 2:30, four leaves had each enclosed a victim. She tried mineral substances and pebbles, but in twenty-four hours neither of the leaves had made any move like clasping these articles. Evidently they knew what was good for them. She wet a piece of chalk in water, and in less than an hour bristles were curving about it, but soon unfolded, leaving the chalk free upon the blade of the leaf. It was found, in making experiments with another species, with a piece of apple, after eleven hours part of the bristles were clasping it, but not many of the glands were touching it. Evidently it didn't like apples as well as it liked beef. The same observer found that when live flies were pinned at half an inch distance from the leaves, the leaves moved toward the insects, and in less than two hours had reached them.

I don't know how to explain it, I don't know how the plant in that case knew the fly was a half an inch away from it, but in some way it did know it, and managed to go over and grasp it.

The *Dionaea*, or Fly Trap, is perhaps, all things considered, the most wonderful plant of which we have any knowledge; though almost all plants become more and more wonderful, the more we study them. The plant is somewhat peculiar in structure, having a dilated bell-like portion, and at the top of this it bears a sort of rounded blade with a kind of enlarged fringe in the centre. This, as you see, bears little bristles, so that when these two sides come together they meet thus: [The points of the bristles passing by each other.] Upon the surface, upon each side are three or four bristles. These are sensitive.

These two sides fit together in such a manner that the action is much the same as an ordinary rat-trap; where you open out the jaws in this way, and if you happen to touch the spring here, the jaws spring suddenly together. The action is almost the same. I have frequently taken a pin and irritated these little hairs and they would clasp with a quick motion, just like a little trap. Now, if an insect happens to alight on this upper portion, and happens to strike one of these little hairs, you see what the result would be; it would be caught. Now, you see why these hairs are made so that they close in that way.

These hairs, by thus closing in, make a prison with little bars. The insect tries to get out, but usually does not succeed. It has been known for a great many years that flies were caught by this plant, so it was called the "Fly Trap."

Botanists looked at it as a curious plant and it was called the fly plant. Mr. Darwin, however, discovered that there was something in the plant more than the catching of flies, and to him we owe very much of the knowledge we have of it. This last two years or so, many facts have come out. We don't know very much about this plant. We do know enough, however, to regard it as far more than a curious thing, it is a wonderful plant, and when we stand before it, we see attributes which we had supposed peculiar to animals alone. It not only destroys flies. It is destroying just as effectually many of our old ideas of the essential difference between plants and animals. Mr. Canby, a botanist, of one of the Southern States, finds that the insect caught as prey is absorbed, so that in one or two weeks nothing but the shell of it remains. The leaf pours out a fluid which is like the gastric juice, and has the power to dissolve the insect. That is what Mr. Canby found out.

Mr. Darwin finds that this fluid is acid in its reaction, just as the gastric juice; that is, not only has it the same chemical reaction, but it also acts as does the gastric juice. Mr. Canby further finds that when the insect has dissolved, in a few days it is absorbed, so that in one or two weeks nothing but the shell of the insect remains. The leaf is then opened and is ready for its second meal.

Mrs. Mary Treat, of Vineland, the same observer before mentioned, last spring made some observations upon three of these plants. Her account reads more like feeding an animal than like feeding a plant:

"May 5th, plant No. 1. Two leaves caught house flies. Another leaf caught a large blue-bottle fly. May 12th. The two large leaves on No. 1 which caught house flies are opening." That is, the flies were dissolved and absorbed and the leaves opened out in a good healthy condition, ready for more flies. "But the leaf which caught the large fly has succumbed." That seems to be very frequently the case; when it has taken an overdose it seems to be taken with indigestion. "May 5th. A strong leaf has closed over an insect almost as large as a squash bug. June 5th the leaf opened. Leaf healthy. Nothing left of the bug but the shell." Entirely dissolved, as you see. "June 14th.

It has Digested the Bug."

The beetle is longer in being digested, and so it goes on. She says: "In this way I managed to get nine beetles entrapped, but only one leaf was strong enough to digest its victim. My favorite plant, the strongest one, from May 1st to October has caught forty insects and digested most of them."

That is, a little plant, only about four or five inches in high, with these leaves three inches in length, a little plant like that catching and digesting forty flies! A strong story,

GOOD HEALTH.

Trichina.

MESSES. EDITORS:—In your issue of a fortnight ago you gave us a long and interesting dissertation on trichina and its fatal effects on the human system. Now could you not kindly inform us whether there is no cure or no preventive for this alarming evil save in a total abstinence from all porcine nourishment? Are we to infer from your article that we must banish the very palatable dish of ham and eggs from our table? Shall we eschew the time-honored dish of pork and beans, so dear to the heart and stomach of every New Englander—and must pickled pigs' feet and soups be tabooed forever? Or, are we to understand that it is only in fresh pork, or that which has been but partially cooked that this terrible parasite exists? In short, does no ordinary preparatory process kill the trichina?

Yours Respectfully,
G. A. HAMILTON.

Virginia City, March 22.

ANSWER:—The trichina will easily succumb to a heat of 212 degrees F. Hence, no danger need be apprehended from pork which has been thoroughly cooked.

THE TOOTH ACHES.—A correspondent says that after suffering excruciating pain from this ache, and having tried in vain to obtain relief, Betty told me a gentleman had been waiting some time in the parlor, who said he would not detain me one minute. He came—a friend I had not seen for years. He sympathized with me, when I told him how sadly I was afflicted.

"My dear friend," exclaimed he, "I can cure you in ten minutes." "How? how?" inquired I; "do it in pity." "Instantly," said he—"Betty, have you any alum?" "Yea." "Bring it, and some common salt." They were produced; my friend pulverized them, mixed them in equal quantities; then wet a small piece of cotton, causing the mixed powders to adhere, and placed it in my hollow tooth. "There," said he, "if that does not cure you, I will forfeit my head; the remedy is infallible." It was so. I experienced a sensation of coldness on applying it, which gradually subsided, and with it the torment of the toothache. Easily tried.

DOCTORS.—There is no danger that the physician will ever become a useless member of society, for the simple reason that instead of decreasing the share of his duties, the culture of preventive medicine—of the knowledge of how to prevent diseases as well as to cure them after they are engendered—must tend to amplify and enlarge the same. His will be the task, not merely to recognize the forms of ails and endeavor to combat their effects, but to look into the future and, through the aid of all circumstances of the present, predict possible evils and point out means of defense. Add to this the constantly increasing knowledge of drugs and their properties, of the wonderful relations of mind and body, of the nature and habits of disease, which science is rapidly developing, and the physician of the future has before him not a narrower but a far wider field for the exercise of his skill.

FOR DIPHTHERIA.—A Mr. Greathhead, of Australia, communicates to the public a very effective remedy for diphtheria. It is simply the use of sulphuric acid, of which four drops are diluted in three-fourths of a tumbler of water, to be administered to a grown person, and a smaller dose to children, at intervals not specified. The result is said to be a coagulation of the diphtheritic membrane, and its ready removal by coughing. It is asserted that where the case thus treated has not advanced to a nearly fatal termination the patient recovered in almost every instance.

AVOID MARBLE-TOP TABLES.—According to the *Herald of Health* marble-top tables are to be avoided. It says: "They are cold, and rapidly absorb the heat and vitality of the body, robbing it of its life. We have heard of one invalid whom the doctor could not cure until one day he noticed she used a marble stand, and suspected it had something to do with her ill health. So he forbade her touching it. Soon she was cured. We know healthy people who feel the twinges of pain in a shoulder by sitting near one. They are handsome, but unhealthy for all that."

DISINFECTANT AND MOUTH WASH.—A weak solution of permanganate of potash will destroy instantly any taint from diseased teeth or imperfectly cleaned plates, and should always be used to rinse spirituous with in hot weather. It is cheap, satisfactory, almost tasteless, not poisonous, and quite free from smell. It may be satisfactory to some to know that this will remove the taint of smoking from the breath if used as a mouth-piece.

TO CURE HOARSENESS.—When the voice is lost, as is sometimes the case, from the effects of cold, a simple, pleasant remedy is furnished by beating up the white of an egg, adding to it the juice of a lemon, and sweetening with white sugar to the taste. Take a teaspoonful from time to time. It has been known to effectually remove the ailment.

How to Become Fleshly.

You would like to be round and rosy-checked. Then go to bed early after having spent the evening socially. Cheerfulness and contentment are the friends of healthfulness. Sleep in a pure atmosphere and in a room into which the sun has shone through the day. Don't be afraid of the night air, for there is no other air at night, and you would certainly die before morning if you did not breathe it; avoid draughts and dampness; sleep as long as you can and get up as soon as you wake, if you feel rested. Drink all the pure cold water you can swallow first, and ride or walk in the open air for half an hour; then eat a breakfast of Graham bread, baked sweet apples with cream, or some other fruit, with a soft, fresh-boiled egg, or a bit of beefsteak and a baked potato, and drink a glass of new milk, if you like it.

Enjoy what you are doing, either for itself or what it will bring you. Breathe as much pure air as possible; bad food and pure air will make flesh faster than impure air and good food. For dinner, eat roast beef or mutton, or rare steak, with bread, potatoes and all vegetables that are relished, a dessert of plenty of ripe fruit, with cream and sugar, but without pastry or cake. If tired, rest a little before dinner, and take a short nap after it. Don't work hard enough to produce excessive perspiration, if you can help it, or until you feel very much exhausted.

For supper, eat oat-meal porridge, cracked wheat, or Graham meal, with cream and fruit, and a fresh roll; or, if you don't feel hungry, take a glass of milk and eat nothing. Drink little tea or coffee, or none at all. Bathe every day to keep the skin clean and in a surprising short time you will grow plump and light hearted. But remember, you must laugh to grow fat.—*Milwaukee Magazine*.

INVERTED TOE-NAILS.—The application of the muriated tincture of iron to the nail and the surrounding ulcerated and granulated surface, once or twice a day, with a camel's hair pencil, will effect a complete cure. As a general rule to apply it once a day, at bed time, will be sufficient. The ulcerated surface heals with astonishing rapidity, and the nail assumes its normal appearance, making a complete cure, in most cases in a few weeks. Paring and cutting the corners of the nail usually do more harm than good.—*Surgical Reporter, Philadelphia*.

USEFUL INFORMATION.

HOW MALT IS MADE.—The grain is first taken up by an elevator run by steam, and is poured into a weighing bin, from which it passes through an automatic arrangement, where the chaff, light heads, dirt, etc., are carried off by the air, after which the good grain passes over a sieve, which separates any other foreign matter which may remain. It is then carried to the storage room by a conveyancer. The grain is now ready for the steeping or soaking tubs in the basement, where it remains from 24 to 48 hours, according to the grain and temperature. After being sufficiently steeped, the grain is removed to the different floors by an elevator and spread out so as to give it time to sprout before being placed in the kilns. It is necessary in the manufacture of malt to have the grain sprout in order that the sugar may be extracted, from which the alcoholic properties are derived. After the sprouting process the grain is placed in the kilns, which have to be kept at a certain temperature and the malt stirred up or turned over several times to prevent its being overheated. It requires fifteen to sixteen days to convert the barley into malt ready for the manufacture of beer.

HOW TO USE A GRINDSTONE.—Common grindstone spindles, with a crank at one end, are open to the great objection that the stone will never keep round, because every person is inclined, more or less, to follow the motion of his foot with his hand, which causes the pressure is always applied to the very same part of stone, and will soon make it uneven, so that it is impossible to grind a tool true. To avoid this, put in place of the crank a small cog-wheel of 13 cogs, to work into the former. The stone will make about 1/7 of a revolution more than the crank, and the harder pressure of the tool on the stone will change to another place at every turn, and the stone will keep perfectly round if it is a good one. This is a very simple contrivance, but it will be new to many of our readers.

BLACKENING SHEET ZINC.—The following is a new process lately discovered for obtaining zinc sheets of a solid black color. The sheet of zinc is cleansed by hydrochloric acid and sand, and then plunged into a solution of equal parts of chlorate of potash and sulphuric acid. A slight velvety-black deposit is immediately formed. The plate is carefully washed with water, allowed to dry, and then plunged into a solution of asphalt in benzine, left to drain, and rubbed with a piece of cotton rag.

BIG GUNS.—Seventy years ago the heaviest naval gun was a thirty-two pounder, weighing two tons and a half, and ten pounds of powder was a charge. A gun now in process of construction at Woolwich, England, twenty six feet and nine inches in length, will weigh eighty-one tons, throw a projectile of 1,250 pounds weight, and requires 210 pounds of powder to load it.

BEEF STEAK ELECTRICITY.—The six Christmas lectures for juvenile listeners at the Royal Institution, London, were delivered by Dr. J. H. Gladstone, F. R. S. He chose for his subject, "The Voltaic Battery." Most of the experiments and teachings were of course too elementary to interest the readers of these pages, but one of the experiments revealed a fact not generally known. He said that in daily life weak electrical currents are at work where their presence is often little suspected; for instance, enjoining a person at dinner to have a silver fork in one hand and a finger upon the steel part of a knife held in the other, it follows that, when he plunges the knife and fork into a beef steak, two dissimilar metals are thereby placed in a moist conducting substance, consequently a voltaic circuit is formed and an electric current flows through the body of the individual between the knife and fork. To prove that this was really the case, he connected a reflecting galvanometer with the knife and fork by means of wires; he then proceeded to cut a beef steak, and the current thus generated deflected the needle of the galvanometer, so that the spot of light which it reflected was seen traveling along the scroen by all the observers.

CREMATION.—The practice of cremation by open-air burning has frequently been referred to as long practiced by the Indians in various parts of the country; but we have no recollection of ever before meeting with a cremation process, as described below. We copy from an exchange: Cremation appears to have been practiced in this country in the ages anterior to its occupancy by our present race. In the region of North Carolina the custom was to cover the body with clay and build a fire upon it, which not only consumed the body, but converted the clay into a hardened mass, or sarcophagus. In the region of Indiana it appears to have been the custom to place the body, with the feet, within an oven of clay, the ashes being left in the receptacle after incineration.

TO CRYSTALLIZE FLOWERS.—Construct some baskets of fancy form with pliable copper wire, and wrap them with gauze. Into these tie to the bottom violets, ferns, geranium leaves—in fact, any flowers except full-blown roses—and sink them in a solution of alum of one pound to a gallon of water, after the solution has cooled. The colors will then be preserved in their original beauty, and the crystallized alum will hold faster than when from a hot solution. When you have a light covering of crystals that covers completely the article, remove the basket carefully, and allow it to drip for twelve hours. The basket makes a beautiful parlor ornament, and for a long time preserve the freshness of flowers.

MEAT AND WINE.—Meat does not oxidize or putrify in compressed air, though it undergoes changes of color, texture and flavor. Certain fermentations may be arrested by oxygen at a high pressure. Wines may be prevented from undergoing acetous fermentation by the action of compressed air. Wine (even new wine) may also be prevented from undergoing any deteriorating change by rapid agitation for 24 or 48 hours under a pressure of two or three atmospheres—in fact wine may be "aged" in a few hours by that process.

TO DO AWAY WITH MATCHES.—A recent French invention, which, it is claimed, will sweep away the match trade, is an electrical tinder box, small enough to be carried in a cigar case. On opening the box a platinum wire is seen, which, by touching a spring, is made at once red-hot, so that it will ignite a cigar. A mesh of cotton steeped in spirits may also be introduced into a tiny cone, and a little lamp is the result. The hidden agency which heats the wire is a miniature electrical battery, set in action by touching the spring.

HOW TO PREVENT BENZINE STAINS ON CLOTHING.—The brown marginal stain generally left after removing a grease spot with benzine, may be prevented by strewing gypsum or lycopodium upon the cloth immediately after removing the spot, as far as the material is moist, and allowing it to remain on until perfectly dry, when the gypsum can be brushed off, leaving the cloth without the usual unsightly rim.

AN excellent way of cleansing soiled Brussels carpet, in the spring when stoves are removed, is to take a bucketful of soft water, with a pint of ammonia added. With this give the carpet a good rubbing, but do not moisten it too much. Immediately afterwards wipe up with a clean dry cloth, and the carpet will be thoroughly clean and free from dirt without shaking.

ALVAN CLARK, the Cambridge telescope maker, who worked ten years to establish a reputation, is getting ready to manufacture an immense telescope for the Austrian Government, and is also negotiating with the trustees appointed by Mr. James Lick for the erection of an instrument in a California university.

A 999 years' lease has just run out in England, and the estate has reverted to the representatives of the original owners. The land is at Woolwich, and was wharf property 1,000 years ago, but was leased to the Crown for military purposes.

COMPOSITION OF WOOL GREASE.—According to Schulze and Ulrich, the hulk of the natural wool grease of sheep consists of compound ethers. A part of alcohols and fatty acids are in a free condition.

DOMESTIC ECONOMY.

Fish as Food.

Fishes yield an almost endless variety of food for man. They furnish a much greater number of edible genera and species than any other class of the animal creation, and from them some nations derive their chief maintenance. The inhabitants of the most northern parts of Europe, Asia and America, where but few slimy plants are found, are compelled to live almost exclusively on fish.

The great bulk of the soft part of fishes consists of voluntary muscles forming the flesh, which are disposed upon the sides of the spinal column—four series on either side. They are soft, pelvical and but little permeated with blood. Fish flesh contains more water than the flesh of either quadrupeds or birds. In many fishes the flesh is mixed with, or covered by, oily or fatty matter, as in the salmon, the herring, the sprat and the eel. This is more abundant in the thinner or abdominal parts than in the thicker or dorsal portions. Hence, the thinnest part of salmon is preferred by epicures. After spawning, the quantity of this oil is greatly diminished.

In the cod and many other fishes, the muscles are arranged in more or less wedge shaped masses, called flakes, which, after cooking, readily separate from each other, owing partly to the contraction of the muscular fibre, and partly to the solution of interposed ligamentous tendinous matter. In the flat or eel-shaped fishes, the flesh has rather a fibrous than a flaky arrangement. The flesh of the whiting, the cod, the haddock, the sole, the flounder, the turbot and other species, is white; hence, they are termed white fish. The flesh of fish is in the greatest perfection for food at the period of the ripening of the milt and roe. It is then said to be in season.

Fried Meats.

This frying of meat is most unwholesome and unprofitable for the eater, however convenient it may be for the cook. It robs it of its juices and hardens its texture. The extreme heat of the fat not only burns the outer layers of the meat, so as to injure their value for nutritive purposes, but also changes the chemical conditions of the fatty acids, giving rise to products which obstruct the breathing and causes ringing of the eyes and nose of the cook, and which are more or less harmful to the eater. The peculiar flavor of the meat is in a great measure lost by frying, and for it is substituted the flavor of the fat in which it is cooked. This fat permeates the fibers of the meat in such a way as to render them less soluble in the watery fluids of the mouth and stomach, and thus causes difficult digestion.

It is to be feared that our cooks have a fatal facility in the use of the frying pan. It is the most mode of preparing meat, and so inferior to every other in its result, that we may reasonably hope that the improvement in this respect will continue. Broiling on a gridiron over a quick fire costs a little more time and trouble, and very likely fuel also; but by this process the juices of the meat are sealed up, to a certain extent, instead of being evaporated, and the nutritive value thereby much increased. The superiority both of flavor and digestibility which broiled meat possesses are perfectly well known. The general substitution of the gridiron for the frying-pan in the hasty cooking of meats, would be most advantageous to the health.—*Herald of Health*.

Apples in Imitation of Ginger.

To three pounds of very hard apples take two pounds of loaf sugar, and a quarter of a pound of best white ginger. Put these in layers (having first sliced the apples in eight pieces and cored them) alternately in a wide-mouthed jar. Next day infuse an ounce of white ginger, well bruised, in about a pint of boiling water; let it stand till the next day. Then put in the apples that have been two days in the ginger. Simmer slowly until the apples look clear. Take great care not to break the pieces.

The following is another recipe, which we find in the *London Garden*: For 4 lbs. of apples take 4 lbs. of sugar, 1 quart of water, and 2 oz. of heat essence of ginger. First pare the fruit, cutting out every particle of core; then shape it to resemble the small kind of preserved ginger. Boil the sugar and water nearly twenty-five minutes, until it is a nice syrup, then put in the apples; be sure not to stir them much; add the essence of ginger (if 2 oz. be not sufficient, add more). It will take nearly an hour to boil, until it becomes yellow and transparent. There will be some pieces that will not clear; put them by themselves, as they will spoil the look of the rest. It will require skimming.

PREPARING POTATOES FOR FOOD.—First, in whatever manner they are cooked, it should be done rapidly—roasted, boiled or fried. Nothing is so soon spoiled by slow cooking as the potato, and should be removed from the fire and placed upon the table when done. Potatoes that are mashed or baked on a dish, are perhaps an exception. The potato may be boiled, mashed and passed through a sieve, and dried upon dishes, and put away for seasoning stews, soups or hash, and are nearly as good as when fresh, for such dishes.

Story of the Black Hills Excitement; Tulamee
County Mines; Mining Decision; Marking Ink for
Linen; Carpentry, Joining, Etc.; Curiosities of Weld-
ing, 218.

Says the Gold Hill News: "Many of the emi-
grants from the East, who intended coming to
the land of the bonanza, are wisely concluding to
continue their journey to California, for the
present, at least. On last Sunday thirteen car
loads of them passed Reno, en route for Sacra-
mento. Some of them stated that advice from
their friends already here and unable to obtain
employment, has caused them to change their
point of destination.

J. A. BELL has discovered in the San Fer-
nando mountains, about 28 miles from Los
Angeles, a large vein of sulphur, being 15 feet
wide and almost the pure article. In the imme-
diate vicinity he found a vein of coal that
would average about five feet in width. The
coal is what is known as black slate, and is
very hard.

ANOTHER steamer is to be placed on the
Feather river, to ply between Marysville and
San Francisco. The keel will be laid at the
intersection of the Yuba and Feather rivers.
The lumber will be brought from the northern
coast, and the machinery will be made at the
Marysville foundry. The steamboat will be
owned by a citizen of Marysville.

THE Lewis District, which is situated about
sixteen miles southwest of Battle Mountain, is
attracting considerable attention, and accounts
from there are exceedingly favorable. A lot of
rock from this ledge recently worked at Winne-
muca, yielded \$2,500 to the ton.

OUT near the Tacoma coal fields has been
found an immense quantity of granite, said to
be as fine as any in the world for building pur-
poses. Also marble of first-class.

OVER 150 claims have been entered on vari-
ous ledges in Josephine county, since the excite-
ment over the tonanza discovery there.

A BAR of bullion valued at \$6,676 was sent
down to this city a few days ago from the Vint
mine, Baker county.

THE miners from all the districts in Utah re-
port vast amounts of ore ready for shipment as
soon as the roads will permit.

The University Collection of Minerals.

We are pleased to state that the extensive
collection of ores and minerals at the State
University, is to be properly arranged and
classified. The Regents of the University have
appointed Mr. H. G. Hanks to a position simi-
lar to that of the Keeper of Mineralogy at
the British Museum, and he will immediately
enter upon his duties.

The collection at the University is very large
and a valuable one, but in its present disordered
state is of no use to the students. The collec-
tion comprises that of the State Geological
Survey, the Voy, the Pioche, and the Hanks
collections, besides a large number of miscel-
laneous material donated by individuals. These
will all be merged into one and be properly
identified, classified and labeled. The labels
will be printed and give the name of the dis-
tinct collection, the name of the donor, etc.

It is the intention to draw from every part of
the Pacific coast, material to add to the present
collection, and classify and arrange everything
in proper order. There are to be three distinct
collections. The first will consist of the finest
specimens of all classes, which will be placed
under plate-glass, properly labeled and identi-
fied, but which cannot be handled, although the
specimens can of course be examined through the
glass. The second will also be a complete one,
and will be labeled and placed in drawers, so
as to be accessible to the students for examina-
tion. The third will be for the purposes of
analysis, exchange, etc.

Mr. Hanks intends giving his whole attention
to classifying and arranging this material, and
will make all exchanges for the University.
He will also make microscopic slides of all the
minerals and rocks. He proposes not only to
collect minerals and rocks, but all sorts of
metallurgical products. People who have any-
thing of interest in these lines will do a great
favor to the University and the State, if they
will forward such specimens as they can, giving
details they think proper to make public. All
these articles will be placed in the museum and
the fullest credit given to the donor. Articles
of this character addressed to the University
Museum, Department of Mineralogy, will be
forwarded free by Wells, Fargo & Co. If du-
plicate specimens are sent, so much the better.

Mr. Hanks says that when time admits and
it is considered essential, careful examinations
or analysis of substances will be made and the
result forwarded to the donor. For instance,
a mineral water, a salt, borax, or peculiar soils,
which are interesting, will be analyzed or
otherwise examined. In making a salt or soda,
sulphate of copper, or any manufactured arti-
cle, if it is essential to know the character of
the special mineral used, Mr. Hanks will ac-
knowledge receipt of the article and give all
the information in his power. In such cases
as it is considered essential an analysis will
be made free of charge. The advanced students
will also make experiments with material of
this character, the results of which will be for-
warded to the donor. They desire to procure
all metallurgical products of whatever character,
such as samples of bullion, slag, tailings, wash-
ings of sluices, etc. Samples of earth from dif-
ferent hydraulic mines are solicited, as well as
specimens of ore, etc., from all mines on the
coast, with such information concerning it as
the donors are willing to impart.

The collection of the State Geological Sur-
vey, now at the University, is very extensive,
but has never been properly arranged. The
Hanks collection, recently purchased by James
Keene, and presented to the University, is all
properly labeled and classified. The Voy and
Pioche collections are both in pretty good or-
der. All of these merged into one, with the
additions made in the next few years, will
make a collection larger than any in the United
States. It is to be hoped that the mining com-
munity will bear in mind the fact that the
University will be thankful for donations, and
that the collection will at all times be open to
the public.

The Regents have made a wise choice in
selecting Mr. Hanks to fill this position. He is a
skillful chemist and assayer, and is as expert
in determining ores or minerals at sight as any
man in California. He has had great experi-
ence in collecting and identifying this class of
material, having made several fine collections
for himself and for other parties. He has been
curator of Mineralogy at the California Acad-
emy of Sciences for some years. With him
this work will be a labor of love, and no one
could take more interest or pride in making the
collection so varied in its character and correct
in its classification. Mr. Hanks has made a
special study of the microscopic determination
of minerals, a branch of science which will in
a few years assume great prominence. He has
now a fine assortment of objects of this charac-
ter, mounted for microscopic examination, and
will take pains to collect and prepare a large
number of slides for the University.

THE tunnel which has been commenced by
the Virginia and Gold Hill water company, to
connect the head of their flume with Mariette
lake, will be 2,900 feet in length, passing
through the main mountain ridge between
Hobart creek and Lake Tahoe.

Land Plaster or Gypsum as a Fertilizer.

The manorial value of land plaster—sulphate
of lime—has long been known and acknowl-
edged. As long ago as when Benjamin Frank-
lin lived and employed his peculiar but most
effective modes of presenting great and im-
portant truths to his countrymen, land plaster
was employed as a dressing upon the land of
our most advanced and intelligent farmers.
That great philosopher once adopted the fol-
lowing characteristic method of teaching the
value of this important mineral as an aid to
growing crops: He selected a large grass field
by the side of a public highway near Philadel-
phia, which rose gradually from the road to
the rear of the field, and staked out upon its
surface the forms of certain letters; within
these forms he sowed freely his favorite fer-
tilizer. As the season wore away the grass
thus prepared soon shot up far ahead of the
surrounding herbage which was not so treated,
until it finally stood out in such bold relief
of luxuriant green that no passer-by could fail to
observe the phenomena, which explained itself
in the magic words—LAND PLASTER. This was
a practical test of the value of the fertilizer,
which fairly spoke for itself in words which
could be neither ignored nor disputed.

The philosophy of this fertilizer—exactly
how it acts upon vegetation—is not fully under-
stood or agreed upon by agricultural writers.
It is well known, however, that it has a great
affinity for ammonia, one of the most fertiliz-
ing agents known. It is this quality which
gives its great value as a disinfectant about
stables, where ammoniacal gas is so abundant.
A slight sprinkling of gypsum on a compost
heap arrests the escaping gases at once, and
the unpleasant volatile ammonia is lost to the
sense of smell. As fast as the ammonia passes
from the mass it is taken up by the sulphuric
acid contained in the gypsum end in combina-
tion therewith forms a sulphate of ammonia
which, when placed in contact with the root-
lets of vegetation, in a not over moist soil,
readily gives up its ammonia as food for the
plant.

Hence it is reasonably supposed that when
spread upon land, without a prior contact with
the compost heap, it collects ammonia from the
atmosphere and conveys it to the plant in the
same manner as already described. Others
suppose that when applied directly to the
land it possesses the power of condensing
moisture during the cool hours of the night,
and imparting its nightly accumulations to the
soil or plant roots during the day. Whether
one or both, or neither of these propositions
are true, there can be no mistake about its
great value as a fertilizer to every species of
vegetation—whether grass, grain, vines or
trees. The experiment of Franklin has been
tried time and again in nearly all parts of the
country, and almost always with the most grati-
fying success.

The conditions of its use are simply a not
over moist soil. In corn or roots it may be
dropped in the hill; but the usual way of ap-
plying it is to sow it broadcast upon the sur-
face—for wheat, as soon after it is up as it be-
gins to show the need of moisture; the same
with grass. For trees and vines it should be
spread freely upon the ground. It need not
be harrowed in when so spread under any cir-
cumstances. We have little doubt but that
this fertilizer would prove of great benefit to
the dry, arid soils of California. We under-
stand that some of our farmers are already ex-
perimenting with it, and we trust some of them
will send us the results of their experiments
as soon as results are reached.

In the best agricultural districts of the East
gypsum has become a staple article among
farmers. They use it as the most reliable
remedy in cases of drouth. A slight dressing
of this, applied to corn in the early stages of
its growth—about the time of its first cultiva-
tion—produces marked results. It is benefi-
cial to all crops in nearly all conditions, es-
pecially in case of drouth; and it is this point
which we would like particularly to impress
upon the minds of the farmers of California,
where drouth is the paramount agricultural
difficulty. This fertilizer may be obtained of
Lucas, Gesner & Co., of this city. See their
advertisement in its appropriate place.

Fona lumbermen have discovered, located
and worked a quartz gold mine on the Fresno
river, opposite to a place called Indian Peak.
They have worked about thirteen tons of ore,
cleaning up nearly \$5,000. The parties have
been offered and refused \$40,000 for their dis-
covery.

ANVICKS from San Bernardino state that the
long lost Gunsight ledge has been found. It
was first discovered on the edge of Death val-
ley by a party of immigrants in 1849. It was
always reported very rich, and specimens of
the ore received confirm all that has been said.

MR. TOLLES is putting in on Gold canon, be-
low Silver City, a revolving sluice for extract-
ing the silver sulphurets from tailings. By the
action of the water passing through the sluic-
e, the blankets are washed every fifteen minutes.

THE Newport mining company of Coos Bay
is buying a tugboat for its own use.

Notices of Recent Patents.

Among the Pacific Coast patents recently ob-
tained through Dewey & Co.'s SCIENTIFIC PRESS
American and Foreign Patent Agency, the fol-
lowing are worthy of mention:

EYELETING MACHINE.—John Coombe, San
Jose, Santa Clara county, Cal. This patent
provides an eyeletting machine, which will
punch the hole for the eyelet, and also fasten
the eyelet in the hole after it is punched, by
means of a single plunger, and without shifting
the article in which the eyelet is to be fastened
after it is once fixed for punching. To do this
properly the inventor provides the machine
with a clamp or holder, in which the article to
be eyeleted is held while the eyelet hole is be-
ing punched and while the eyelet itself is being
inserted and fastened. A sliding die, which is
operated by a lever, has a hole for the punch to
pass through in making the eyelet hole, and
also a short standard upon which the eyelet is
set previous to punching the hole. The ar-
rangement of the hole and eyelet standard is
such that by operating the slide both can be
brought under the plunger as required.

IMPROVED FAUCET.—William C. Bussey, San
Francisco. The applicant for this patent
claims to provide a faucet for drawing liquids
from casks, etc., without the employment of
either a rotating plug or spigot. Into a hollow
tube which is driven into the cask is secured
a short plug through which a hole is made
communicating with a hole in the stem of the
tube and through which the liquid passes.
Over one end of the plug is slipped an India
rubber tube which is squeezed together by a
clamp consisting of two jaws just below the
end of the tube, thus regulating the
flow of the liquid. A spring fits around the
end of the stem and a screw extending through
both jaws of the clamp close and regulate the
tube by compression.

CAR COUPLING.—Thomas J. Habbell, Yount-
ville, Napa county. The many terrible acci-
dents which have occurred to brakemen and
others engaged in coupling cars have rendered
any invention which would do away with risk of
maiming or killing men engaged in this busi-
ness as among the most valuable to be imagined.
The inventor claims to have invented a perfect
self coupler and uncoupler. The operation of
coupling as described, goes far to prove that
the claim of the inventor is a just one. It is
automatic in its operation, and by means of a
lever worked from the platform, the cars can
be uncoupled and separated without danger to
life and limb.

ADJUSTABLE DEVICE FOR BRAKE BARS.—Robt.
J. Knapp, Half Moon Bay, San Mateo Co.,
Cal. This invention relates to an improvement
on wagon-brakes, and consists of a method of
adjusting the brake-bar by which the distance
lost by the wear of the brake-shoes, can be
readily taken up. Brake shoes, of course, be-
come very worn in time, and as the short arms
of the operating levers have a slight move-
ment, as compared with its long arms, it will
be seen that where the block becomes worn the
bars will drop too far. To remedy this defect
this brake-bar was invented.

TIRE UPSETTER.—Quentin Cincinnati Tabbs,
Windsor, Sonoma county. The object of
this invention is to provide an improved man-
ner of upsetting metal bands and tires for the
purpose of shrinking or reducing their diam-
eter. The machine is operated by a leverage
power which can be increased to any required
degree.

AT THE SAVAGE mine the two new hoisting
engines to take the place of the old incline
engine are in place, and will be ready to start
up in a few days. These engines are each of
200-horse power, and will work the mine to the
depth of 4000 feet with the most perfect ease.
The new wire rope for the incline has arrived,
and is being placed on the big drum ready for
use. This drum is of the same pattern as that
used by the Crown Point Company, is three feet
longer, and is tapering from one end to the
other, so as to wind the rope with greater ease
than the old style. The rope is two inches in
diameter, and weighs over 25,000 pounds, the
last 1500 feet gradually tapering to 1 1/4 inches
in diameter.

THE Battle Mountain Measure for Measure of
the 20th, reports a new mining discovery by J.
L. Higgins and E. Bickett, four miles south-
west of Battle Mountain. Assays of the ore
run from \$111 to \$300 the ton in silver.

CHEYENNE is endeavoring to get up a Black
Hills gold excitement in opposition to Sioux
City. Old miners and trappers in Utah, who
have been in the Black Hills, pronounce the
discovery of gold there a great humbug.

THE yield of gold from placers and quartz in
Montana for 1874 is placed at \$2,360,170, di-
vided as follows: Placers, \$1,554,007; quartz,
\$496,170.

SINCE January 1st, San Francisco has re-
ceived over 6 000 flasks of quicksilver from the
various producing districts of California.

A New Milling Machine.

The Tanite company of Stroudsburg, Pa., exhibited at the last Fair of the American Institute in New York, a new machine in which an emery wheel is used, for the first time, for surfacing files and sad irons, finishing anvils, nuts, ribs, keys, slide valves, straps, slides, cross-heads, and in short, for accomplishing the majority of work now surfaced on the ordinary planer, milling machine, or shaper. It will be remembered that the emery wheel made by the above-named corporation is of the solid type, and a brief review of the advantages claimed for it may appropriately precede the mechanical description of the large, fine engraving herswith presented, of the machine above referred to.

sad iron, which is shown secured in the chuck on the table, G. In addition to performing this labor, the gearing, immediately driven by pulley, C, also rotates the vertical shaft, H, which in turn transmits power to the cones on its right. These again (through the medium of a belt, other cones, and further suitable interposing mechanism) revolve a vertical rod, I, the lower end of which is fitted with a globe joint. Its upper extremity carries a pinion, which, by means of the handle, at J, may be thrown into action with one or the other of two racks under the table, G, so that the latter, by manipulating the handle as required, may be caused to travel automatically to and fro under the emery wheel, and over such distances as the dimensions of the work make necessary. The hand wheel, at K, allows of similar movement to be imparted to the table by hand, in circumstances where the automatic motion is not desired.

ing the employment of the diamond tool unnecessary. The cut made is much deeper than has hitherto been considered possible to accomplish by the emery grinder. The manufacturers also claim that in those articles in which first quality iron is used, on account of its being more easily worked, the use of their wheel will soon save enough valuable metal to pay for a machine. From a careful examination of the apparatus, these advantages appear to us to be well substantiated.

These machines are manufactured by the Tanite Company, and are sold on this coast only by H. P. Gregory, 14 and 16 First street, San Francisco.

Sewing Machines.

It is the general impression that through the refusal of Congress to extend certain sewing

ing machines. The cheap machines are now sold at a price as low as the makers can afford to sell them, and the first-class machines are not going to reduce their prices on account of the refusal of Congress to extend the patent mentioned.

The first-class machines are manufactured by companies which have large establishments, fitted up at immense expense, with all the necessary machinery to turn out machines at the lowest possible price. To successfully compete with these companies, it would be necessary to expend very heavy sums for purchasing machinery; and even then the wealthy companies own the larger number of patents for improvements, and can make them cheaper than those who have to pay for the use of these. This, of course, would in a great measure prevent others from competing with the richer companies.

It is a combination of patented improvements

THE TANITE COMPANY'S IMPROVED MILLING MACHINE.

The solid emery wheel performs the office of a rotary file, the cutting edges of which never grow dull. It is hard and travels steadily at a high speed, the latter exceeding, with safety that of the grindstone, while the emery cuts faster and lasts longer than the sand. Being composed of an artificial mixture, its grit is more even than that of the natural substance. Finally, the solid wheels are successfully used for putting the cutting edges on tools of all descriptions, and they may be produced of any shape, fitted for any special work.

The clearness of our illustration gives an excellent idea of the details of the machine. The driving belt acts upon the pulley, A, secured to shaft, B. The latter at its left hand extremity carries another belt, leading to a counter shaft attached to the floor (represented detached, and lying on the right of the machine), whence a third belt returns to the pulleys, C, and a fourth to the blower shaft, D. Through suitable mechanism, the pulley, C, actuates the slotted crosshead, E, the revolution of which communicates, by the rod, F, reciprocating motion to the main shaft, B, imparting to the emery wheel, represented on the right hand extremity of said shaft, a transverse movement across the

The mode of operation consists in adjusting the work in the chuck to the proper elevation and starting the machine. The surface of the sad iron, for example, is thus carried under the wheel, and at the same time the latter is drawn across it; and this continues until the motion of the table transports the object out of the action of the grinder. The workman then gives the hand wheel, shown at L, a part of a turn, thereby moving a fine screw which passes through an arm on the table, thus slightly elevating the latter, so as to give new surface for the tool to take upon. The handle, J, being shifted, the work travels back under the wheel, and so the operation is repeated as often as is desired, or else a new article is substituted after one passage under the emery. To avoid injury to tools and workmen, a small suction blower, with the necessary pipes and an enlarged receptacle in rear of the wheel, is provided, and so arranged as to draw away all dust, while at the same time to be easily removed for setting the work. For keys and similar small articles, a different chuck (see sample in the foreground of the engraving) is needed.

The machine, it is claimed, allows of using the wheel to its full capacity, while protecting the same against uneven wearing, thus render-

machine patents, we will have cheaper sewing machines hereafter. Many persons think also that the large companies, like the Wheeler & Wilson, Grover & Baker, Weed, Florence, etc., will have to reduce their prices from fifty to seventy-five per cent., on account of competition. Now this is a mistake, for first-class sewing machines will probably be no cheaper for some time to come. The reasons for this are simple, though not generally understood.

In the first place the patent which Congress refused to extend was for the four-motion feed, which is only one of a large number of patents under which the various machines are manufactured. Still, this feed is used by all of them. The refusal to extend this patent will permit other machines to use the four-feed motion without having to pay royalty, but all the first-class machines are protected by a large number of other patents; while the ordinary low-priced machines have been compelled heretofore to use the common feed or pay the royalty to the owners of the patent, they can now use the improved feed free, but we do not see how it is going to break the price of first-class sew-

which make the first-class machine, not one patent. The wealthy companies have made it a point to buy up all the good patents themselves, and they keep patenting every improvement of any importance. This enables them to keep the best machines in their hands. As these machines are improved from time to time, in several cases the whole machine has been changed for the better as new patents were added. Any one can now make a sewing machine of old-fashioned character, using patents which have run out, but they do not manufacture a first-class machine such as most people want when they buy. Any agent will say that a simple change will have the effect of selling thousands of machines, so the inferior machines have little chance against those which have all the latest patented improvements.

Timber is being buried in the Consolidated Virginia mine at the rate of 6,000,000 feet per annum, and in all the other mines in like proportion. The Comstock lode may well be said to be the tomb of the forests of the Sierras.

The Eberhardt mill at White Pine will shortly start up again.

AMMONIA!

For Washing and Cleaning Purposes.

For Sale by all Grocers.

This article is universally used in Europe, and recently
introduced for general family use in San Francisco and
neighborhood, is already in great demand. It is now the
intention of the manufacturers to introduce it all over the
Pacific Coast, at prices which will bring it within the reach
of every household.

It is unequalled for cleaning Woolen Fabrics, Outlets,
Carpets or Crockery; for Scrubbing Floors, Washing Paint,
Removing Grease Spots, Shampooing or Bathing.

It renders water soft, and imparts a delightful sense of
coolness after washing.

DIRECTIONS.—For Laundry, use two to four table-
spoonfuls to a wash tub of water. For bathing, use one
tablespoonful in the bath tub. For removing grease spots,
apply with a brush, undiluted, and wash with water after-
ward. For stimulating the growth of plants, use a few
drops in every pint of water used in watering.

PRICE.—Per Pint Bottle, 25 cents; per Quart Bot-
tle, 40 cents; per Half Gallon, 75 cents.
Also, SULPHATE OF AMMONIA for chemical pur-
poses, fertilizing, and the preparation of artificial manures
AMMONIACAL PREPARATION, for the prevention and
removal of boiler scale. CRUDE AMMONIA, for general
manufacturing, and PUR LIQUOR and AQUA AMMO-
NIA for chemical and pharmaceutical purposes.

Manufactured by the

SAN FRANCISCO GAS-LIGHT CO.

ewwhp

WATER TANKS of any capacity, made entirely

Inventors, model makers and mechanical mechanics
and students, will find the work valuable far beyond
its cost. Published by DEWEY & CO., Patent Agents
and publishers of the Mining and Scientific Press.
Price, post paid, \$1.

Averill Chemical Paint,

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR
APPLICATION—requiring no thinner or dryer, and will
not spoil by standing any length of time.

It is cheaper, more durable, more elastic, and pro-
duces a more beautiful finish than the best of any
other paint.

It will not Fade, Chalk, Crack, or Peel off, and will
last twice as long as any other paint.

In ordering White, state whether for Outside or In-
side use, as we manufacture an Inside White (Flat) for
inside use, which will not turn yellow, and produces a
finish superior to any other White known.

Put up in 1/4, 1/2, 1, 2 and 5 gallon packages, and in
Barrels. Sold by the Gallon.

For further information send for Sample Card and
Price List, or apply to the office.

OFFICE and DEPOT: FAOTORY:

117 Pine Street, near Front. Cor. 4th & Townsend Sts.

3v9-cow-hp-1y SAN FRANCISCO, CAL.

This is a Sure Cure for Screw Worm, Scab
and Foot Rot in Sheep. It also kills Ticks,
Lice, and all Parasites that infest Sheep.

Prevents scratching and greatly improves the quality
of the wool. One gallon of the Dip properly diluted
with water will be sufficient to dip one hundred sheep,
so that the cost of dipping is a mere trifle, and sheep
owners will find that they are more repaid by the im-
proved health of their flocks.

This Dip is guaranteed to cure when used according
to directions, and to be vastly superior to Carbolic
Sublimite, Sulphur, Tobacco, and other remedies which
have heretofore been used by farmers.

Circulars sent post paid, upon application, giving
full directions for its use, also certificates of prompt
cure of sheep growers who have used large quantities of
the Dip, and pronounce it the most effective and reliable
known Cure and Preventive of Scab and other kindred
diseases in Sheep. m13-bp

Ayer's Cherry Pectoral,

For Diseases of the Throat and Lungs, such
as Coughs, Colds, Whooping Cough, Bron-
chitis, Asthma and Consumption.

The few compositions, which have won the confi-
dence of mankind and be-
come household words,
among not only one, but
many nations, must have
extraordinary virtues. Per-
haps no one ever secured so
wide a reputation, or main-
tained it so long, as AYER'S
CHERRY PECTORAL. It has
been known to the public
about forty years, by a long
continued series of marvel-
lous cures, that have won
for it a confidence in its vir-
tues, never equalled by any other medicine. It still
makes the most effectual cures of Coughs, Colds, Con-
sumption, that can be made by medical skill. Indeed,
the CHERRY PECTORAL has really robbed these danger-
ous diseases of their terrors, to a great extent, and given
a feeling of immunity from their fatal effects, that is
well founded, if the remedy be taken in season. Every
family should have it in their closet for the remedy and
prompt relief of its members. Sickness, suffering and
even life is saved by this timely protection. The pru-
dent should not neglect it, and the wise will not. Keep
it by you for the protection it affords by its timely use
in sudden attacks.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.
To Supts. of Quartz Mills and Mining Men generally:
We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburgh Manufacturers
have been compelled to add largely to their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce Shoes and Dies superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered,
flying from under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the largest
mills on the Pacific Coast, and all who have used them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness on first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amalgam
by absence of iron dust and chippings, and a saving of
75 per cent. in freight. It takes 60 days to fill orders
from the manufacturer East. Price 16 cents per
pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

TEATS' PATENT FURNACE
For Roasting, Desulphurizing, Chloridizing
and Oxidizing Ores, etc. For the reduction of
Gold, Silver, Lead and other ores, saving a larger per-
centage, at less cost, than any other invention now in
use. Chloridizing Silver ore more thoroughly, in less
time, with less fuel, salt and labor; also roasting Lead
ore preparatory to smelting, better and cheaper than
any other invention. The Furnace is so constructed
that one man, of ordinary ability, tends five or more
furnaces; controls them with ease; adding heat or air;
stopping or starting at will; changing and discharging
with ease. Also, Patent "Conveying Cooler," for con-
veying and cooling roasted ores, heating the water for
amalgamation and the rollers at the same time. Saving
the large space in mill (covered with brick or iron),
and the labor of two men per day, exposed to the poi-
sonous chlorine gases. Also, Patent Air Blast "Dry
Kiln," for drying ores direct from the mine or breaker,
saving fuel and labor heretofore necessary in drying
ores for dry pulverizing. For description refer to
MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874.
For particulars address
D. B. MILLER & CO.,
No. 12 West Eighth Street, Cincinnati, Ohio
Circulars, &c., will be furnished, if required.

uable tables for computation of assays in Grains
Grammes, will be sent free upon application.
7v25-4f **JOHN TAYLOR & CO.**

Varney's Patent Amalgamator.
These Machines Stand Unrivaled.
For rapidity pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repair. The constant and increasing de-
mand for them is sufficient evidence of their merits.
They are constructed so as to apply steam directly
into the pulp, or with steam bottoms, as desired.
This Amalgamator Operates as Follows:
The pan being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.—
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing a regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.
Settlers made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.
Mill-men are invited to examine these pans and settlers
for themselves, at the office, 229 Fremont Street,
San Francisco.

Gila Silver Mining Company.

ENTRORS PRESS:—This mine has done remarkably well since date of last writing, and it is now looking better than at any time since its incorporation, with every prospect of improvement largely exhibited wherever opened.

There is now a vein defined in outline and accurate in formation, with the distinctive features that are strongly indicative of permanence and character. The south drift on the main incline is now in on its course about 25 feet, through ore of an excellent quality. The vein is about two feet thick, between walls which are well formed, smooth and clean, and descending at about an angle of 60°, the hanging wall exhibiting the same formation as before, but the foot wall shows quartz, lime and quartzite, at alternate distances with talc, manganese, iron, and other minerals that are well-known companions of silver ore, found in greater abundance than formerly. The vein at the furthest end of this drift was beginning to expand, and I have no doubt that when a few feet more southward it will open out considerably. The ore found here continues rich as formerly. Drifting is continued to the right hand parallel with the main tunnel, and a considerable quantity of high grade ore extracted. The stratum is now about three feet thick, and is descending and leading obliquely across the main tunnel, at a point about midway between the main winze and the end of the tunnel, thus showing its connection with the lode, as does all of the ore on this lead. The inside winze sunk at the furthest end of the main tunnel, where the ore body opened out and gave signs of going down, has attained an incline depth of about 30 feet, all the ore of a very high grade (\$867), susceptible of being easily reduced.

The vein is fully six feet thick between walls at the bottom and is the best formed portion of it which has been thus far uncovered. Here are found every characteristic of a true fissure vein, with walls smooth and perfect, and the ore running in a solid vertical strata, as deposited by nature, thus considerably proving the fissure theory, and establishing the fact that the ore coming from the deep ones is not a new surface deposit as might have been supposed.

The ore is chiefly chloride of silver and quartz highly mineralized and easily worked. The connection from this point to the drift extending from the out-croze will be made by Wednesday, which will greatly facilitate operations, by giving plenty of pure air and passage way for powder, smoke, etc. Work was commenced on the outside tunnel on the 9th of March with three 8-hour shifts, and is steadily progressing, showing excellent ore indications, inside the outer rim of the porphyry formation, oxide of iron and other ferruginous matter impregnating the sides and face of tunnel. A couple of pieces taken for assay test are highly mineralized, and will show well in the precious metal. We'll send result as soon as completed.

A substantial blacksmith shop has been built within the past week, for picks, drills, and other matters. A boarding house has also been set in motion, giving the men a chance to procure good board at \$9 per week; five Indians also are employed as sorting ore as extracted from the mine and one packing water from the spring down at the town for the use of men in the mine in which there are twenty-five at work. The contract for hauling the ore from mine to mill has been let.

The mill is now ready and has been since the 10th, and had steam up to test machinery which is found in proper working condition. Wood contracts have also been let, and already about 40 cords at the mill, and probably 100 cords cut, which will be brought in during the ensuing week.

A few assays have been made, showing 3 per cent. of lead, some iron and copper, but not enough of any of them to interfere with milling. The mill is expected to be in motion on the 17th without fail.

Reveille, March 13, 1875.

California Railroad Items.

A large meeting of the responsible citizens of San Buenaventura and representatives from Santa Barbara was held on the 29th ult. at San Buenaventura, to take the initiatory steps to secure the building of a broad-gauge railroad through Santa Clara valley from San Buenaventura, to connect with the Southern Pacific near Lyon's station. The citizens pledge themselves to do all in their power to accomplish the desired end. Parties who are simply able to build and equip the road have said that if the people along the line would do their duty they would connect us by rail with San Francisco inside of two years. A committee has written to the parties pledging the hearty support of the people. The following named gentlemen constitute the committee appointed: E. A. Edwards, T. Wallace More, L. C. McKeeby, L. D. Chillon, M. H. Gay, N. W. Blanchard and T. R. Baird.

The new railroad from Vacaville to Winters is progressing rapidly. Grading is completed for half the distance, and by means of a new machine which has just come down from Sacramento, the work has been going forward at

the rate of a mile per day. The machine is worked by ten horses, and looks something like a header. By the term of the contract with farmers, the railroad must be completed and cars running on the 19th of September, or \$30,000 of subsidies will be forfeited. The country through which the road takes its way is very level, and there will be no heavy cuts or fills. Sweeney creek will have to be bridged two or three times and Putah once. The former creek is small, but the latter will require a longer bridge than it does where crossed by the California Pacific, near Davisville.

The Santa Clara Echo says that it is rumored that a movement is on foot for the construction of a narrow gauge railroad from San José or Santa Clara to Santa Cruz. The route suggested is by either the Santa Cruz or Stevens' creek passes, either of which is very practicable. Rumor also has it that an effort will be made to have the road constructed by the way of Menlo Park; but the route that way would not be so favorable. The building of this road would be a good thing for Santa Clara county.

The Surveyors of the new Sonoma and Marin railroad commenced work in San Rafael on Tuesday. Subscriptions to the enterprise now amount to \$15,000 per mile, and it is to be pushed forward rapidly to completion. Mr. Wickersham, the President, has informed parties that he had purchased a short road leading towards San Rafael from Petaluma, and would put the remainder of the route under contract at an early day.

The managers of the narrow gauge railroad connecting Salinas valley with the ocean at Monterey, distant 18 miles, have resumed operations, after a suspension of several months, caused by the washing away of the trestle-work piling across the Salinas river. They have now two Baldwin locomotives on the road, weighing twenty-three and twenty-one tons respectively.

A NATURAL grade has been found for a railroad on an air line between Colusa and Chico, without a bridge or filling, and it is said that the road will be built in time to carry the fall crop.

General News Items.

THE great topic of the week has been James Lick's revocation of his deed of trust pertaining to his immense estate, valued at above \$4,000,000, on public enterprises familiar to all Californians. He has, having unexpectedly regained his health, changed his mind, and desires to obtain control of his property. The trustees appointed by him to superintend the disposition of the estate under the trust refuse to resign. How the case will terminate is doubtful. The lawyers, of course, expect a "fat thing" and if it goes into the courts their expectations will be realized.

W. F. STOREY, editor of the Chicago Times, was sentenced to ten days imprisonment by Judge Williams, of the County Court, for constructive contempt. A writ of supersedeas, however, released him after a few hours incarceration.

PLACED in a prominent position in the new Congregational church at Woodland, is a card with this inscription: "Use no tobacco in this church." Attendants at that church are expected to eschew evil.

EMINENT lawyers are of the opinion that if the late decisions of United States judges and United States commissioners on the new Civil Rights bill, be sustained on appeal, that with the exception of the jury clause there will be nothing left of it.

A SHOOTING affray occurred on Los Alamos Rancho, about fifteen miles from Guadalupe last Sunday, which resulted in one man being killed and one badly wounded.

THERE was a fire at Benicia, Tuesday morning, burning the house of William Melrose and destroying the lives of three boarders—Wm. Finnerty and two men named Shea and Hanson.

FIVE hundred trees have been planted in the Court-house square, Woodland,—90 acacia, 90 eucalyptus, 100 pine, 100 cyprus and 20 poplar. They are doing well.

THERE is trouble again on the Mexican border. An additional cavalry force has been ordered to the Rio Grande with orders to arrest all marauders.

VICE-PRESIDENT Wilson has admitted to an interviewer that he was a candidate for the presidency.

THE orthographic mania has reached San Francisco. They had a spell of it at Bethany church, Tuesday evening.

Rumor states that a fine prospect of coal has been discovered within three and a half miles of town.

SIX hundred immigrants arrived by the overland train Wednesday.

TOBY Rosenthal's great painting "Elaine" is on exhibition in this city.

THE Mariposa folks are jubilant over a weekly mail.

GENERAL Spinner, treasurer of the United States, has resigned.

GOON Friday was generally observed by business men in the East.

INNOCENTIARISM is prevalent in Marysville.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Industrial Items.

THE Pacific Mail steamship company and Union and Central Pacific roads combination have agreed on a new through freight tariff, which went into effect on the 5th inst. The rates per 100 pounds are: First class, \$6; second class, \$5; third class, \$4; fourth class, \$3; class A, \$2.50; class B, \$2; class C, \$1.75; class D, \$1.50. The steamship rates are as follows: First class, \$4.50; second class, \$3.50; third class, \$2.50; fourth class, \$2.25; class A, \$2; class B, \$1.75; class C, 1.50, class D, \$1.30.

THE Central Pacific railroad company have decided to construct a railroad from Galt, in Sacramento county, to Ione city, in Yuba county. The engineers have been instructed to take the field at once, and the orders are to have the road in operation within one hundred days from this date.

THE Reno (Nev.) Journal is talking of the Truckee river as a water power, and asserts that it is peculiarly adapted for the manufacture of paper, on account of the purity of water and freedom from mineral impregnation.

OPERATIONS have been commenced at the upper end of the North Anaheim canal, Los Angeles county, and the workmen are scattered over three miles of ground, pushing the work forward with all rapidity.

THE surveyors for the new Sonoma and Marin railroad commenced work in San Rafael on Tuesday. Subscriptions to the enterprise now amount to \$15,000 per mile, and it is to be pushed rapidly forward to completion.

An organization has just been formed in Santa Clara county, under the name of the "Hay-Growers Co-operative Union of California," which has for its object the producing, buying and selling of hay.

At a meeting of citizens of San Diego on last Saturday evening, it was resolved to organize a joint stock company for the purpose of boring artesian wells throughout the county.

A new steamer line to Puget Sound ports was inaugurated this week by the departure of the Los Angeles, which will call at Victoria with mails and passengers, up and down.

CALIFORNIA tobacco has taken old Virginia by surprise. A sample was generally commended in the Exchange at Richmond, and \$16 was refused for one hundred pounds of it.

GILROY claims to have furnished 2,500,000 feet of the 10,000,000 feet of lumber which was consumed in this country last year.

CASTROVILLE wants a beet agary. The Argus says the lands in that vicinity cannot be surpassed for beet growing.

THE population of San Bernardino county has increased over 500 during the past six months.

P. G. WIGINGTON is planting forest trees on his ranch on Owen's creek, Merced county.

BRICKS are scarce in Bakersfield.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch. Dated Washington, D. C., March 30, 1875.

FOR WEEK ENDING MARCH 16, 1875.

CLAMP APPARATUS FOR CONNECTING STREET CARS, ETC., WITH ENDLESS TRAVELING DEVICES.—William Eppelsheimer, S. F., Cal.

PROCESS OF OBTAINING BORACIC ACID FROM BORATE OF LIME.—Ferdinand Formals, S. F., Cal.

COMBINED PARASOL AND WHIP.—John Perrins, S. F., Cal.

CHARING IRON FOR VEHICLES.—Gilbert Smith, S. F., Cal.

WINDMILL.—Albert H. Southwick, S. F., Cal.

RE-ISSUE.

Pantaloon, etc.—Jacob W. Davis, Reno, Nev.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

THE building of a tailings flume from the Consolidated Virginia mill to the Carson river is contemplated. The flume would be eight or ten miles in length. After all has been taken out of the ore that can be got out by means of pans, settlers, agitators and blasket sluicing, the tailings still assay \$8 to \$10 per ton.

THERE are several counties in Idaho which comprise more space than many of the Eastern and Southern States.

THE Cloverdale mine has made its first shipment—twenty flasks—of quicksilver.

JUSTICE AT LAST.—The public were far in advance of the medical profession in recognizing HALE'S HONEY OF HOREHOUND and TAR as a specific for consumption, coughs and colds; but at last the Faculty are doing justice to the great antagonist and conqueror of Pulmonary Diseases. The country druggists generally report that the local physicians are prescribing it in preference to all the old plimmonics, and that the result is an immense increase in the percentage of cures. PIKE'S TOOTH-ACHE DROPS—Cure in one minute.

The Mining & Scientific Press.

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi.

As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millmen, and Metallurgists in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Smeltermen, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

DEWEY & CO.,

No. 224 Sansome street, S. F.

From an Inventor.

The following letter, which was recently received from an old client of Dewey & Co., now residing in one of the Eastern States, speaks for itself:

GENTLEMEN: It was through your house that I secured my first patent, and although I have since done business here in the Atlantic States with the ablest patent solicitors—gentlemen who have done me justice—yet I have often regretted that you were too far off to advise with me in my cases. It has taken a longer time with every patent I have taken out since I left California and came East, than in the cases you prepared for me in San Francisco, which is certainly very creditable to you.

By the way, one of my patents has passed the ordeal which is the essential test of a patent's value. I mean that of a trial in the courts, and it stood the battling of one of the best lawyers in the country. The specifications and claims were completely made out and there was a perfect comprehension of its principle during the trial. Since giving it this test we thought that we would make it even stronger, if possible, and submitted it to one of the best patent solicitors for advice. After a careful examination of the case he advised us to let it alone as it stood, saying that whoever made up those papers understood their business. I then informed him that they were drawn up by Dewey & Co., of San Francisco, and he replied that he knew you very well by reputation.

Very truly yours,

L. L. SAWYER.

Meriden, Conn., May 16, 1874.

Designing and Engraving at This Office.

We are prepared to do fine Wood Engraving for illustrating Landscape Scenery, Buildings, Machinery, Works of Art, Manufactured Articles, Trade Marks, Seals, Etc. We have a first-class

Machine for Engraving

A portion of the work, which can be finished thereby more perfectly than by the eye and hand alone. Our patrons can depend upon first-class work always, and at reasonable prices. Samples can be seen at our office.

DEWEY & CO.

SECOND EDITION—REVISED AND ENLARGED.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings.

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by

DEWEY & CO.

place of business, San Francisco, California. Location of works, Butte Township, Sierra county, Cal. Notice is hereby given that a meeting of the Board

Notice is hereby given, that the meeting of the Board of Directors, held on the 8th day of March, 1875, on assessment (No. 4) of one dollar (\$1) per share, was taxed, assess-

the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, northwest corner Pine and Sansome streets, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of April, 1875, will be delinquent and advertised for sale at public auction, and unless payment is made before sale, will be sold on Monday the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

LOUIS VESARIA, Secretary.
Office, Northwest corner Pine and Sansome streets, San Francisco, California.

Manhattan Marble Company of California.—Location of principal place of business, San Francisco, California. Location of works, Oakland, Alameda county, State of California.

Notice is hereby given, that at a meeting of the Directors, held on the 30th day of March, 1875, an assessment (No. 2) of five dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary of the company, at his office, Nos. 13 and 15 Fremont street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 30th day of April, 1875, shall be deemed delinquent and advertised for sale at public auction, and unless payment is made before sale, will be sold on Monday the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

L. L. ALEXANDER, Secretary.
Office, Nos. 13 and 15 Fremont street, San Francisco, California.

Oreans Mining Company.—Location of

Location of works, Grass Valley Township, Nevada
County, California.
Notice is hereby given that at a meeting of the Board

Location of works, Grass Valley Township, Nevada
County, California.
Notice is hereby given that at a meeting of the Board

Location of works, Grass Valley Township, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Trustees of said corporation, held on the 16th day of March, 1875, an assessment (No. 3) of one dollar per share was levied on the said corporation, and the same is payable immediately, in gold coin of the United States of America, to the Secretary, at the office of the company, Room 8, No. 316 California street, San Francisco, California. Any person who has not paid said assessment, shall remain in default on Wednesday, the 21st day of April, 1875, will be advertised on that day as delinquent, and unless payment is made on or before that day, the same shall be sold at public auction, on the 1st day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expense of sale.

W. F. NESMITH, Secretary.

Office—Room 8, No. 316 California street, San Francisco, Cal.

Silver Sprout Mining Company—Principal place of business, San Francisco, State of California.

Location of works, Kearsege Mining District, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of February, 1875, an assessment of one cent per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the Company, in San Francisco.

Any person who has not paid said assessment, shall remain in default on the 17th day of April, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made on or before that day, the same shall be sold at public auction, on the 1st day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expense of sale.

OVER \$3,500 PER MONTH SAVED

BY THE USE OF

Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1875.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

- 1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).
- 2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).
- 3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.
- 4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimonial. For further information you are at liberty to refer to,

Yours respectfully,

JAS. H. CROSSMAN, M. E.

409 California street, or Cosmopolitan Hotel.

SAN FRANCISCO, February 10, 1874.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.

MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to this company has been over \$3,500 per month more than with the blankets and buddles formerly in use.

O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.

J. HENDY, Esq.—Dear Sir:—Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.

As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection.

E. R. BURKE, Superintendent.

THE PACIFIC COAST CONSOLS.

Interest Payable Monthly, in Gold and Silver.

A MINING, REAL ESTATE AND LAND COMPANY.

Incorporated February 12th, 1875.

Capital Stock, --- \$27,000,000.

IN CONSOL SHARES OF \$1 EACH.

Of which 13,500,000 shares constitute the Sinking and Investment Fund. Interest payable monthly at the rate of 12 per cent. per annum. Certificates of CONSOLS share's receivable at their par value in exchange for any Mining, Real Estate or Landed Property of the Company.

Directors: T. PHELPS, W. S. REYNOLDS, B. M. FETTER, L. K. GOODMAN, J. H. BATES.

Certificates of CONSOLS only issued at the rate and proportion of 50 per cent. of the cash valuation of property to be represented in CONSOLS shares. Dividend paid from profits and sales of property, and only on shares of CONSOLS that have been issued for property valued and entered on the books of the Company.

Principal Office, 528 Kearny Street.
Principal Depository Agency, --- Bank, San Francisco.

Depository Agencies for payment of interest on CONSOLS will be established in the principal cities in the United States and Canada, and in London, as when required.

Interest payable on the 5th of each month at any Depository Agency of the Company.
Certificates of Interest-bearing CONSOLS, Class A, First Series, issued for Mining Property in Washoe, Storey and Lyon counties and on the Comstock Lode, in Nevada, will be ready for delivery to subscribers and purchasers on or before April 10th 1875.

Orders for not less than one hundred shares of CONSOLS, with the purchase money required (\$1 per share), may be sent through Wells, Fargo & Co.'s, at our expense. No certificate of stock issued for less than twenty shares. All orders must be addressed, "Office of the CONSOLS M. R. E. and L. Company, 528 Kearny street, San Francisco."

T. PHELPS, President.
W. S. REYNOLDS, Secretary.

THE AMERICAN TURBINE Water Wheel.

Power Pledged Equal to any Over-shot Wheel Ever Built.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{4}$ 50.08; $\frac{1}{2}$ 69.64; $\frac{3}{4}$ 78.73; $\frac{1}{2}$ 82.63; $\frac{1}{4}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

Hydraulic Mining in California.

No. 20.

Loss of Gold and Quicksilver.

It is difficult to arrive at a correct estimate of the loss of gold in hydraulic washings. In mines where coarse gold predominates the loss cannot be so great as where gold in fine particles, commonly called flour-gold, constitutes the principal yield. Hydraulic mines, however, must chiefly depend on the latter gold, which is diffused through the hills and mountain sides.

The loss of quicksilver in the best conducted hydraulic mines is from 12 1/2 to 15 per cent., and the loss of gold, in many cases, can hardly be less. Even if almost all the heavier particles of bright gold are saved, still there is in all mines a proportion of rusty gold, which is not attacked by quicksilver, and is very liable, on account of the reduction of its specific gravity by the adherence of foreign matter, to be carried off in the sluice-stream.

In most cases the tailings of a hydraulic mine become public property, and are, therefore, a total loss to their original owners. How great this loss is may be evidenced by the yield of only a small portion of these tailings under subsequent working.

There can be no doubt whatever that generally too much gravel is washed for the supply of water. We need only to argue from the most primitive mode of gold-washing, namely, the washing with the pan, to gain the strongest proof that by the washing of enormous quantities of gravel in a stream of thick and muddy water, great quantities of the finer particles of gold are lost. To save such gold in a pan requires not only a skillful hand, but a change of water, so as to offer the least resistance to the settling of the particles at the bottom of the pan. Considering, then, how easy it is to carry on certain mechanical operations on a small scale, which are altogether impracticable on a large one, we must conclude that the difficulties of saving the flour-gold in enormous sluices, running rapid streams of thick and muddy water, must be increased, though not, perhaps, in direct proportion to the difference between the quality of material washed. That it is desirable to extract the gold as completely as possible from the gravel-deposits, which, though immense, are nevertheless exhaustible, needs no demonstration; the only means will be a greater supply of water. With an ample supply of water a system of sluices could be introduced which would separate the finer gravel, black sand, etc., from the main stream and carry this finer stuff, with a new supply of pure water, alongside the main sluice. A medium grade of six inches to twelve feet of the main sluices would suffice not only to carry out such a system of separation, but to establish under-currents and drops for finer gravel, even to a greater extent than the present system of sluice-washing permits.

We will suppose that sluice-boxes on a grade of six inches per twelve feet and for a distance of 5,000 feet are established; that, furthermore, the natural fall of the main outlet permits no higher grade.

At the point where main sluices leave the tunnel (the length of which is immaterial), a grating, such as described under the heading of under-currents, is inserted in the bottom, flush with the pavement of the sluices. The bottom of the main sluice, below this grating, which may be from fifteen to eighteen inches in width, forms the bottom of the box which receives the water, fine gravel, etc., falling through the grating. To give fall to this box, a false bottom on a grade of one-half inch per foot is inserted. This box leads into (or is continued in the form of) a smaller sluice box, running alongside the main sluice and on a grade of only four inches per twelve feet.

To facilitate the flow of this strained material, and to make up for the loss of grade, a jet of pure water is injected by a small pipe into the receiving-box below the grating, assisting thus in keeping this box clear and in washing the strained gravel, etc., in a pure stream of water.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner in Mining Statistics.

A nugget of pure gold, weighing eight ounces, was last week discovered in the Granite Tunnel mine, El Dorado county.

Work Done by Burleigh Drills.

We give herewith a detailed account of the results accomplished with the Burleigh drills and air compressors during the month of February at the New Almaden mine, in the tunnel near the "hacienda." The report is made by J. B. Rudol, manager of the mine. The dimensions of the tunnel are seven feet six inches by seven feet six inches, and the rock passed through has been a strata of hard rock of a limestone class, interspersed with thin seams of quartz. The seams cross the tunnel at right angles. The operations for February (24 days) were as follows: Holes drilled four feet deep, 300; average per day, 25.04. Holes forced, 786; average per day, 32.75. Holes missed, 9. Hercules and Giant powder used, total, 818 pounds; average, 34.08; average per foot, 6.59. Black powder, total, 287 pounds; average per day, 12 pounds; average per foot, 2.31. Car loads removed, 358; average per day, 14.91. Cords wood, 31 1/2; average per day, 1.29. Feet driven, 124; average per day, 5.17. Hercules or Giant powder is used for the cut as shown in the diagrams and fired by electricity, driving out the wedge of rock. Side holes are then charged with black powder, which squares the drift.

The cost per foot was \$21.90, in which account is included all expenditures, as follows: Labor, including repairs, \$1,418.56; material, including fuel, track, pipe, explosives, etc., \$1,307.89. Total, \$2,726.45. The tabular statement herewith gives the details of daily work for the month. We publish it to show that the account has been systematically kept, and also as a guide to others keeping similar accounts. It should be stated that the day shift each day commences work at 7 A. M., and stops at 5:30 P. M. The night shift goes on at 5:30 P. M., and is off at 5:30 A. M.

Previous to the introduction of these drills the tunnel was run 7x7 in size—by hand labor. Nine men on contract in October made 40 feet at \$23.29 per foot, and the same number of men in November made 33 1/2 feet, at a cost of \$18.49 per foot. Work with the drills on measurement 7 feet 6 inches by 7 feet 6 inches was commenced in January, when 108 feet was made at a cost of \$22.89. It will be seen from this that even at an equal cost the amount of work done by the drills in a given time is more than trebled.

FURTHER EAST.—The new hoisting machinery of the North Consolidated Virginia mine is completed, and everything is in line working condition. The Gold Hill News thinks that the company has shown good judgment in the starting of their shaft to the eastward, on the line of the C & C and Chollar and Savage shafts, it being evident that nearly all the mines on the Comstock will eventually have to shift their hoisting works further to the east.

Blaisdell's Improved Railway Tie.

The invention illustrated herewith is an iron tie, designed as a substitute for the wooden tie originally employed, and also to provide a strong and elastic support for the rails, while constituting a portion of a permanent way.

Face.

Section.

The peculiar form of the cast iron body of the tie, clearly shown in Fig. 1, is calculated to give strength and stability, and, at the same time, to insure economy of material. At each end are formed rectangular sockets, open at the top and at the outer extremities. The lower parts of said sockets are flanged in order to retain rubber blocks, A, in the sectional view, Fig. 2, above which wooden blocks, B, are laid. On top of each of the last, the rail chair is placed. The chair is made in two parts, so as to be adjusted readily to grasp the rail between the lip and foot plate. Overlapping portions of the body, C, together with the bolts entering the wooden block, securely hold the chairs in position. Passing longitudinally through the entire tie is a truss rod, D, which is set up outside the wooden blocks with nuts and washers. The apertures through which this rod enters the metal part of the tie are made sufficiently large to allow the depression of the blocks when the rubber yields to superincumbent pressure.

It will be seen that the rubber blocks give an elastic support to the track, tending to nullify the results of jarring and compression. The wooden blocks serve a similar purpose, and may be used alone when any great degree of elasticity is not required. The chairs may be adjusted to hold rails having flanges of varying

width; and owing to the firm bearing afforded by the abutting surfaces, they are retained in position with the least possible number of spikes.

The sloping contour given to the surface of the tie enables, it is claimed, the wheels of a train, in event of running off the track, to mount and pass over, the ties, instead of crushing the same, as might otherwise occur. For

IMPROVED RAILWAY TIE.

Further particulars address the inventor, Mr. George D. Blaisdell, Cambridge, Vt.

THE mining fever has spread into Maine. Penobscot county now boasts its silver mine, and is ready to compare ugggets with Newburyport. Ore is said to have been discovered in Dexter, which careful scientific analysis shows will pay out \$360 silver and \$12 gold per ton.

H. J. Booth & Co. are at work on a mill for the California mine, which will be the largest mill on the Comstock, and, consequently, in the world. It will have 70 stamps (10 more than the big Consolidated Virginia mill), 42 pans, and will be run by an engine of 1,200 horse-power.

A FIRE broke out in the San Bruno mine at Mosquito, Calaveras county, March 29th, and to extinguish it the mine was closed, the shaft and all other openings stopped. It had not been opened at last accounts, and the damage is not known.

IMMENSE deposits of coal have recently been discovered in East canyon, of Utah, within five miles of the Utah Western railroad, causing considerable rush and excitement.

CORRESPONDENCE.

The Treatment of Ores of the Precious Metals.

EDITORS PRESS:—The constant efforts made to improve the methods in use for the reduction of ores of the precious metals demonstrates the fact that considerable inconveniences are experienced in the economical treatment of these ores. The careful study of the chemical and physical condition of the metals, and their peculiar behavior under external and adventitious circumstances, may help to explain what appear as discrepancies in many metallurgical operations. The observance of those laws that govern disposing causes, that frequently interfere in chemical reactions, may also lead to the establishment of rational hypothesis. While great caution is necessary in discussions of subjects of difficult solution, yet some latitude may be allowed to the student searching for data to base technical operations. Numerous experiments have been made to determine the relative force of chemical actions of various reagents with a view to solve some of these difficulties, constantly met with by the metallurgist. Slight causes often turn the scale when the opposing forces do not greatly differ. To narrate the result of a long list of inquiries to base the present case upon, would exhaust the patience of the reader; therefore, only such matters will be mentioned that may be of practical value, which this paper is intended to treat.

Concerning the decomposition of antiferrous sulphides by roasting; the question has been asked, if amalgamable gold can be obtained. We answer, no. The so-called desulphurized ore is far short of the theoretical requirements of the law, even when conducted by the most improved methods in use. A smelting heat would be fatal for the purpose of amalgamation. If we examine some of the elements that the metallurgist has to contend with, there may be found some explanation that may lead to the solution of some of the difficulties frequently met with. One of the most insidious of these bodies is that of sulphur; this substance bears great resemblance to that of oxygen in its chemical relations, the basic character of the proto and intermediate oxides and sulphides, and the great attraction existing between that body and most of the metals. The less oxidizable metals frequently hold sulphur with great obstinacy. Long continued roasting reduces the sulphides to a lower condition to a proto salt, which has strongly marked basic qualities. The metals possessing strong attraction for oxygen, an oxide is formed; the complete removal of the whole of the sulphur by the ordinary calcination may be questioned, more particularly in presence of hydrogen vapour. The rationale of the chemical changes induced by treatment of sulphurets by the Statefeldt and Bruckner furnaces has been given; to some the explanation is not wholly satisfactory, yet sufficient evidence is given to show that a double interchange of elements is necessary to effect complete decomposition. The laws of substitution regulating the formation of compounds are of sufficient importance to merit careful consideration. The complex changes brought about by the action of variable quantities of compound bodies often present great difficulty to the student in search of data; he finds it necessary to pause to examine such disposing causes that would otherwise lead to the belief that the order of things was reversed; nor is it surprising when passages are met with in chemical writings to this effect: that oxygen replaces chlorine, hydrogen, bromine, etc., to form oxides; again, chlorine draws out oxygen from metallic oxides to form chlorides, etc. An example is seen in the relative force of chemical attraction existing between hydrogen and iron for that of oxygen. A slight alteration of temperature is sufficient to cause a change of state. The more negative metals, even in excess, similar effects take place. The application of a solution of hydrochloric acid to the photographic image offers an example. Further, here is a multitude of curious phenomena and indirect actions connected, to be considered before satisfactory formulae can be arrived at. These slight allusions to important chemical changes as they occur in the treatment of ores of the precious metals, it is hoped, will prepare the way to render that process intelligible.

This new method is dependent on the fact that the incandescent sulphuret particle, if placed in an equivalent of glowing atmospheric oxygen, decomposition will immediately ensue. The resulting bases are acted upon in a manner which is determined by their respected attractions for the elements employed.

Ores containing sufficient sulphur for heap roasting may be stacked and roasted in the open air. Sulphur will be expelled, together with arsenic and volatile bases, and an intermediate sulphide produced. This is a cheap method which greatly aids the subsequent fine grinding. Ores containing less sulphur, unfitting them for this treatment, should be finely ground and heated to redness in a reverberatory furnace of especial construction, that consists of several hearths, placed one directly above the other; also inclined or zig-zag and communicating air chambers or pipes are made to traverse through the interior, then proceeding to a coil or pipes heated to redness by a separate furnace, and so arranged that it can

be detached when necessary. This hot chamber receives air from the blast, which, circulating through the heated pipes, attains a high temperature, this being brought to the vicinity of the bridge of the reverberatory. The ore is fed from the top; it soon attains some degree of heat, and is then pushed to the second floor, and so on until it arrives at the lowermost, in a state highly incandescent, and falls into a hopper near the bridge. This is supplied with a feeding apparatus which allows the ore to fall gradually on the current of glowing air, that carries it immediately into a chamber a few feet high, striking against the upper end or hood. It is deposited in the outer chamber. Thus it will be seen that a complete decomposition of the sulphuret particle is dependent, not on the time of contact with atmospheric oxygen, but the necessary equivalent for that purpose. It is always well to have an excess, which guards against any tendency to cinder.

The end of this last chamber communicates with a dust condenser. This, too, has some important features which must be described: This condenser consists of a cylindrical or other form vessel, with a sieve at one end, and of sufficient dimensions to hold a quantity of irregular shaped pieces of metal scraps, waste tin, or even stoke or coke that will allow gas or water to pass through it. This vessel is charged with these materials and placed in a tank with an inclined bottom, and the whole put under a chimney or in communication with it. A fine spray is allowed to play upon the top of these pieces of metal. The draught from the chimney draws the dust and permanent gases up from the bottom, sufficient space being allowed between the cylindrical vessel and the tank for the purpose. The large surface of wet material, constantly irrigated, rapidly condenses the dust, which is carried by the current to the tank, and is discharged outside and collected, if necessary, while the gases pass up the flue. This simple condenser occupies but little room, and giving place to more costly condensing chambers, and may receive the appellation of the "dust trap."

The red hot decomposed ore deposited in the above chamber enters a feeding hopper and falls on a current of chlorine generated from a retort outside, that keeps a small chamber charged with that gas. A small aperture will keep up circulation, and will regulate the pressure. The addition of a little nitrate of potassa to form hyponitric acid will greatly aid the chemical action. With ores containing less sulphur or base material this method is highly advantageous. Silt may be employed in the hopper instead of the gas, and some advantage may be obtained by using, in conjunction, the hyponitric acid.

It is necessary to take a retrospective glance of the chemical changes induced by this method of treatment of the sulphides. By roasting in heaps in the open air a lower sulphide is formed, analogous probably to the black oxide, and containing qualities of a sulphur base. This is in contact with atmospheric oxygen in excess, and incandescent ignition immediately takes place, with the formation of sulphurous and sulphuric acids, and oxides of the more oxidizable metals and bases. Those possessing less attraction for oxygen form a sulphur base. There are a number of complex changes brought about by disposing causes. Their nature and action will be omitted, as they do not greatly interfere in practical operations; yet mention must be made of one of the most potent, namely, heat. This determines chemical action with great avidity. This is seen when an equivalent of atmospheric oxygen and sulphur are brought in contact with the sulphuret particles and blast, while an excess of the latter prevents any tendency to scarification by acting on the metal and bases. Ores containing zinc, lead and copper, readily yield in smelting by employing the appropriate fluxes. Simple roasting amalgamable gold is not obtained, no doubt from the condensation of sulphuretted hydrogen on its surface, generated by the decomposition of the metallic sulphides. The contact of chlorine or the hyponitric acid used as suggested is sufficient to remove this evil. It owes its existence to the decomposition of water, the hydrogen combining with the sulphur and oxygen with the metals. The second treatment or chlorination has some advantages; the ores are acted upon in a manner which is determined by their respective attraction for oxygen and chlorine; giving rise to a method employing approximate equivalents of chemical bodies used in their reduction.

Something might be said here regarding the subsequent treatment and reduction of the chlorinated silver ores, but will be deferred for a future opportunity. J. TUNBANOX.
Nevada City, Cal.

Capital Wanted in Utah.

EDITORS PRESS:—Well knowing and fully appreciating the untiring energy and enterprise of Californians, I would call their attention to the consideration of two opportunities for the investment of capital in this vicinity, which it would seem are first-class in all respects. The first and most urgent want for successful smelting in Utah, is the procuring of fuel at a reasonably low price. All the coke used here is obtained at St. Louis or beyond, at the enormous cost of \$35 per ton, delivered in Salt Lake City. The draft on our smelters for this item in the past year was something near one million dollars, and making the cost of smelting approximate closely to \$25 per ton. In West Mountain mining district, of which Bing-

ham is the center, we have a vast amount of argentiferous galena, of too low grade to be worked at so high cost and return a satisfactory profit. And there is no necessity for this state of things continuing. There is an abundance of coal within a short distance, shown by analysis to be adapted to cooking as well as that from which we are procuring our supply. Henry S. Pool, F. R. S., to whom specimens of San Pete coal were sent for analysis, reports:

Volatile matter and ash.....35.50
Coke.....64.50
By Fred. Clusdet, of London, England:

Coke.....62.10
Ash.....10.64
Volatile matter.....27.36
With scarcely a trace of sulphur. Analysis in New York and Philadelphia equally favorable. The Southern Utah railroad is completed to within forty-five or forty-six miles of the mines that are opened, and the road is being extended; yet there are known to be undeveloped mines much nearer the route.

Here is a chance for the profitable employment of capital that ought not to go begging. The business is capable of an indefinite expansion, the twenty-five or thirty smelters already in operation, with the certainty of great increase of the number, would give a surance of success to a large investment. A reduction of only twenty-five or thirty per cent. in the cost of coke would enhance the output of ore in this and the adjoining districts to at least double the present quantity in a year. The facilities are first-class in the San Pete region for the purpose under consideration. A feeble attempt was made in this direction last year, but whether relinquished or not we are not informed.

Equally certain of successful returns would be investment in concentration works, situated at intermediate points between the mines and the great number of smelters in Salt Lake valley. Two or three failures have been made, or if not failures, only partial successes, have been made in that line. No reason can be assigned why there is any peculiar difficulty in concentrating our ores, and we must look for the cause of the failure to defective manipulation.

This business also would be susceptible of enlargement to an unlimited extent, and would be second to none in importance as a paying investment. It should be mentioned in this connection that concentrating works on a huge scale were erected near Salt Lake City two years ago, that would have been of infinite benefit to the country as well as profitable to the owners, but by an unaccountable blunder the location was so ill-advised as to defeat the entire purpose. WILLIAM TEAL.

Biogham, Utah, March 27.

Yosemite.

Cost of Travel and Roads to Yosemite and the Big Trees.

The time for tourist travel to the above named places will probably soon commence, and some idea of the cost of the trip and the routes and distances will be interesting. Perhaps no one knows any more on this subject than Mr. J. M. Hutchings, of Yosemite Valley; fame, and he writes as follows to the *Bulletin*: "There are now two excellent wagon roads completed to the Yosemite, so that persons can ride in a carriage to the hotel doors, if they so elect. One is via Big Oak Flat, and the other via Coulterville. Another, between Clark and Moore's (now known as the Big Tree station) and the Valley, is in course of construction, and will probably be completed to the 'Hermitage' early this season.

Routes, Distances, Etc.,

Will indicate the starting point and general course to be taken.

First—Via Stockton and Big Oak Flat to Yosemite:

San Francisco to Stockton, by rail..... 91 miles
Stockton to Milton, also by rail..... 28 "
Milton to Chinese Camp, by coach..... 28 "
Chinese Camp to Hotels in the Valley..... 69 "

Total, (by rail 119 miles, coach 88 miles),.....207 "

This route lies directly through the Tuolumne Grove of Big Trees.

Second—Via the Calaveras Grove of Big Trees to Yosemite:

San Francisco to Stockton and Milton, by rail, 119 miles
Milton to Murphy's Camp, by coach..... 30 "
Murphy's Camp to Big Tree Grove, 15, and back 15, by coach..... 30 "
Murphy's Camp to Sonora, by coach..... 14 "
Sonora to Chinese Camp, by coach..... 14 "
Chinese Camp to Hotels in Valley..... 60 "

Total, (by rail 119, coach 145 miles).....264 "

This route is through a portion of the mining districts, and a very picturesque country, and, like the former, embracing the Tuolumne Grove of Big Trees.

Third—Via Merced and Coulterville to Yosemite:

San Francisco to Lathrop, by rail..... 82 miles
Lathrop to Merced, also by rail..... 67 "
Merced to Coulterville, by coach..... 43 "
Coulterville to Hotels in the Valley..... 43 "

Total, (by rail 139, coach 96).....235 "

The Merced Grove of Big Trees is directly on this route.

Fourth—Via Merced and Mariposa to Yosemite:

San Francisco to Lathrop and Merced, by rail, 139 miles
Merced to Mariposa (mail route), by coach..... 46 "
Mariposa to Big Tree Station, by coach..... 26 "
Station to Big Trees and back, horseback..... 12 "
Big Tree Station to Hotels in the Valley, by coach and on horseback..... 27 "

Total, (by rail 139, coach and horse 111 miles) 260 "

There is an excellent trail constructed down the wild canon of the Merced river, and which, being generally below the snow line, opens the great valley to the tourist in winter, and prevents the "snow blockade" of former years. This route would be by Mariposa and Hitt's cove; or by Coulterville and Brewar cove to the valley, and gives about thirty miles of horseback riding.

Admonitory Suggestions.

The following, the result of experience, if kindly taken, will be found valuable:

Go in by one route and out by another. The reasons for this will be obvious to every one.

Avoid "round trip tickets," for if they save a trifle (and there is really little if anything saved) they often put you to trouble that is not trifling. And it frequently happens that you meet friends in the valley whom you would like to journey with, but who may be going one way while your ticket takes you another. When private teams are preferred to stages, have your agreement in writing and clearly expressed. Of course, take this with you.

Select genial companions, leaving all "growlers" at home, as one such will destroy the comfort of a whole party.

Do not hurry, especially when going. Any one whose time is limited should go alone, or with others similarly situated.

Eschew large trunks (unless you are intending a long visit) and all needless articles. Take inexpensive yet comfortable clothing, including one change of underclothing (there are laundries there,) strong boots, not necessarily heavy, well broken to the feet before starting. Ladies should carry an extra pair. They should also provide themselves with one short dress—a neat Bloomer would be found the best.

Add twenty-five per cent. to your carefully considered estimate of the expenses of the trip.

Be and keep jolly, taken even any little mishap good-naturedly.

Take the best, and make the best, of everything.

If any man tells you, "I am the only authorized agent for the sale of tickets; the route I represent is the only one," don't you believe him—in anything.

Probable Expenses of the Trip.

Fare from San Francisco and back, say, about.....\$60
Board, \$3.50 per day, by the week..... 20
Horse hire, guides, tolls, etc., about..... 20

Total.....\$100

Horse hire in the valley is generally about \$2.50 per day. Guide, which includes his horse, wag-s and board, \$5 per day to the party. To insure careful attention and safety on mountain trails, large parties should have one guide for every five or six persons.

As several excellent horse trails have been made by private persons to picturesque points that were formerly inaccessible on horseback, tolls are charged as follows:

To Glacier Point.....\$1 00
To Nevada Fall (Snow's)..... 75
Nevada Falls to Glacier Point..... 75
Foot of the Upper Yosemite Fall..... 50

Total Tolls in and around Valley.....\$3 00

There is also a charge of \$1.50 each person on both of the new roads opened last season; but this toll is included in the fare charged. The information is for those only who drive in their own private teams.

Lastly, stages will commence running early in April. Private teams at any time desired. Ed. Harrison, 140 Montgomery street, is agent for the direct route via Chinese Camp, also for that via Calaveras Big Trees. Thos. Houseworth, No. 9 Montgomery street, Lick house, is agent for the McClellan & Co. stage via Merced and Coulterville. S. Miller, No. 3 New Montgomery street, under Grand hotel, is agent for the route via Mariposa and the W. Shuburne, Chapman & Co. stages via Coulterville. Private teams can be had of Doak & Dunning and Captain Johnson of Stockton, and of M. McClellan and Washburne, Chapman & Co., Merced. Each of these will have their agents—all duly authorized, I presume—in this city.

NEW PROCESS FOR WORKING GOLD ORES.

"We do not know anything officially," says the *Grass Valley Union*, "about a new process of working gold bearing quartz, which has recently been put in operation in this county. We only know that works have been established, and are in operation, between this place and Nevada City, which will treat ores in a new way. The works are located near Glenbrook race-course, half way between this place and Nevada City, and have been in operation some three or four weeks. It is said the process there used will work quartz in lumps, without crushing and without concentrating sulphurets, in the simplest manner. Not a color of gold escapes the new process. The lumps of quartz put into the works are dissolved, so to speak, in a few moments, and all the gold and other metals are extracted and returned, less cost of working, to the man who carries quartz to that place. And the cost of working, it is said, is much less than by mill process. This we give as a rumor, and we do not know that the rumor is correct. If the new process is all that rumor says it is, then the millenium has about arrived. At all events, the new operators are paying their own way and are asking no one to put up a cent for them. We noticed, yesterday, several sacks of quartz going up to be turned into gold. It may be, in the course of time, that we can catch a definite idea about the new manner in which quartz here is to be hereafter worked by this new process.

MECHANICAL

PROGRESS.

Big Guns and What They Will Do.

The London Standard has an article about big guns, which gives some startling facts. It says: "England is now building a ship to carry twenty-four inches of armor, and she is making a gun which will be eighty-one tons in weight. Unquestionably, the ship is splendidly designed. So also is the gun, which we are to have ready some time about next July, and which will doubtless turn out to be a wonderful weapon. Artillerists speak of the coming monster as 'an awful gun.' Crowds assemble at the forge whenever one of the huge coils is to be pummeled by the new steam hammer at Woolwich arsenal. Even in the making of this 33-ton gun, masses of iron weighing twenty-eight tons, at a welding heat, have to be laid under the hammer. For the larger gun, an incalculable mass of forty tons has to be fetched out of the fire and duly hammered. The furnace has the capacity of a cottage, and the tongs by which the glowing cylinder is lifted out of its burning bed, weigh no less than thirty tons. A steam crane bears the whole weight of tongs and coil, and everything proceeds without accident or hitch of any kind. At night the sight is truly grand, and well repays those spectators who take the trouble to be present.

"This great gun, which is being constructed at Woolwich arsenal, has a bore of sixteen inches diameter, and twenty-four feet in length. It will fire a ball weighing one hundred and sixty-six pounds, propelled by three hundred pounds of powder, the range being over six miles." But the Standard says this is not all that can be done, and after speaking of the practicability of a twenty-inch bore, it asks: "Why should we stop short of that which might be gained at some period or other? Let us contemplate the further step at once. Why not have a gun with a bore of twenty-four inches—simply two feet. The weight would be two hundred and seventy-five tons, the charge of powder would be one thousand pounds, the weight of the projectile nearly two tons and a half, and the range eight or nine miles! This is not a mere dream, but a perfectly practicable piece of work. The cost would probably be a trifle less than \$500 per ton, or about \$125,000 for the entire piece. In weight of projectile, such a gun would probably be something more than a 5000-pounder. Perhaps, when we had made such a gun, we might think we had gone far enough. As for the armor, the projectile of the 275-ton gun would penetrate three feet of iron, with corresponding backing. The length of its bore would be thirty-six feet. That of the 'Woolwich Infant,' of thirty-five tons, is thirteen and a half feet, the bore of the thirty-eight ton gun being three feet longer. The eighty-one ton gun, as already stated, will have a bore of twenty-four feet. The 'Woolwich Infant' has a maximum external diameter of rather less than five feet. The eighty-one ton gun will measure in this respect six feet. But the two hundred and seventy-five ton gun would measure nine feet. Such would be its full height if lying flat on the ground. A tall man would come a yard short of the top of the gun, the latter simply lying on the bare earth without a carriage." The Standard intimates that this will be the most popular gun ever to be used.

Plumbago—Preservation of Iron.

In these days of general diffusion of chemical knowledge, it is scarcely necessary to state that the "black lead" or "plumbago" of commerce, is not lead at all, or any compound of its composition. Neither is it a carburet of lead, and it includes no lead whatever in iron, as is sometimes stated. It is simply carbon. Pure plumbago is pure carbon, impure plumbago is impure carbon. Its proper name is graphite, that is, writing stone. We may venture to describe it as the softest of all true solids, and have often pondered wonderingly upon the apparently unnoticed, but very curious chemico-mechanical paradox that the hardest and softest of all the solids existing upon the earth are, chemically speaking, the same substance, graphite and the diamond being both carbon.

It is this wonderful softness, combined with persistent solidity, that enables us to smear it over any other solid surface, and thus obtain a solid paint, all body and no medium. For the uses of casting, to which it is commonly applied where its application can be readily repeated and where it is not exposed to the direct action of water, it is unrivalled as a protecting film for iron. Its chemical action, so far as it does act when cold, is reducing or anti-oxidizing. Its color and tone are so familiar to iron that Mr. Ruskin himself could scarcely make any aesthetic objection to its use, and the film is so marvelously thin that it obliterates nothing. There does not appear to have ever been any attempt to estimate the thickness of a well-brushed film of graphite, but it would seem that if a hundred strata of such films could be piled in contact with each other, their combined thickness would fall short of that of the thinnest oil leaf.

Graphite or plumbago is also extensively used for the lubrication of machinery, and for crucibles, being entirely incombustible through being pure carbon. It is, when pure, a true metallic carbon, and the iron of four to twelve per cent. that it contains is purely a mechanical combination.

A New Plan for Heating Dwellings.

SCIENTIFIC

PROGRESS.

Is the Earth Approaching the Sun?

Heating by hot air or steam is a wasteful use of fuel. It is poor economy to heat air or water and rely upon the cooling of those elements for our supply of warmth. We overlook the fact that heat will travel quite as well alone as in company.

Radiant heat, says the *Scientific American*, the sort required for perfect heating, obeys the same laws as light. By proper arrangement of reflectors and lenses, heat radiations can be massed into beams of parallel rays, and sent where we will, with little or no wasting. It is not until the radiations are arrested that they become manifest as heat; a fact put to practical use two thousand years ago, when Archimedes burnt the fleet off Syracuse with mirrors. A stream of heat vibrations, intense enough to fuse gold, would pass through a stream of ice without effecting it, provided the air in the tube be sufficiently pure and dry. There appears to be no good reason, therefore, why we should not warm our houses by the direct distribution of pure heat, and so gain all the benefits of an open fire in each room, with none of its disadvantages.

Briefly described, the plan would involve a central furnace; a system of tubes leading to the different rooms terminated by radiators in each room; a system of reflectors to throw the heat of the furnace into the conducting tubes in parallel rays, with other reflectors of the bends and angles of the tubes to direct the course of the radiations properly. The radiators in the rooms might be placed so that every portion would be flooded with light, yet no part be heated beyond what would be enjoyable. As nothing would enter the room from the furnace save pure heat, the effect would be like that of a room warmed by direct sunshine. The surplus heat of the furnace might be utilized in warming an abundant supply of fresh air let in from outside doors; a steady circulation being kept up, from the ventilating chamber through the rooms, by the draft of the furnace. We should have then (theoretically) perfect heating combined with perfect ventilation, and at the same time the most economical combustion of our fuel.

Possibly there may be mechanical difficulties to prevent the successful carrying out of a plan of house heating of this sort. We do not anticipate any, and the advantages it promises, on the score of health, comfort and economy, certainly justify its trial by any one possessing the requisite means. The plan could be easily tested in the laboratory of any institution having a few lenses and reflectors. These suggestions might afford a good opportunity for inventors to exercise their ingenuity.

Photographic Parasols and Wearing Apparel.

We have already alluded to the use of the photographic art for the ornamentation of parasols. A late number of the *Photographic News* contains an article upon the same subject in allusion to its more extended application. The same process, says that journal, is now being further employed for printing handkerchiefs and shirts; and we were fortunate in seeing the other day some examples of what can be done in this delicate fancy printing process. Some handkerchiefs shown us had at the corner two or three butterflies most charmingly impressed, the images having evidently been taken direct from the insects themselves. Other fabrics bore sketches, evidently reproductions from woodcuts and engravings, obtained and printed by a photo-mechanical process, all of them being of a most delicate nature, such as could hardly be secured from blocks or lithographic stones. Photographic portraits of various kinds were also to be seen impressed upon fabrics in the same way; but these, perhaps, can scarcely be called novelties, neither was the result so successful as in the case of the other objects we have mentioned. The prints were undoubtedly all produced by fatty ink, and, would, no doubt, be very permanently printed upon the fabric. This method is much simpler and more satisfactory than printing in the ordinary way by silversalts; for very great care has to be exercised in the latter case, and failures are far from infrequent, the dressing in the fabric being most difficult to remove and apt to discolor the silver print. Moreover, there are the troublesome operations of salting and albumenizing, and flattening the stuff, which is by no means an easy proceeding, any more than the examination of the print in the pressure frame. This photo-mechanical printing upon fabrics is certainly an art to be cultivated.

THE BAXTER CANAL STEAM-BOAT.—Experts and the public are becoming more and more convinced of the eminent practicability of the Baxter canal steamer. It has been determined to put on a daily line of these boats to go through from Buffalo to New York. These boats will have twice the speed of carriage by horse boat, and each steamer will carry the tonnage of a full railway freight train, and will deliver in quick time, say three or four days at most, in New York.

A NEW BELTING MATERIAL.—In engineering shops in Germany a new kind of belting is being adopted. It is made from hair, presumably that of the alpaca, and is delivered by the makers in a single piece without seam. It has a coating which consists principally of minium. It is spoken of as most satisfactory, and as being more durable than either gutta-percha or leather.

Gases Evolved by Molten Iron.

SCIENTIFIC

PROGRESS.

The Universal Diffusion of Heat the End of All Energy.

The author considers that gases evolved from molten iron come from three sources. 1. They were dissolved by the iron while melting in the furnace. 2. They were dissolved by contact of the molten iron with the air. 3. They were dissolved by contact of the molten metal with the mould.

1. The evolution of gas from gray iron is small; the gas consists chiefly of hydrocarbons or carbon iron oxide. From white iron more gas is evolved, together with little particles of iron, which are oxidized in the air. Spiegeleisen evolves a peculiar white fuming gas, which contains silica, and is probably silicon fluoride.

The author thinks that the poorer an iron is in combined carbon, the more readily does it absorb gases containing carbon, while the richer it is in carbon the more readily does it dissolve gases containing hydrogen. The primary cause of the evolution of those gases which have been dissolved in the furnace he traces to the diminished pressure under which the iron exists, as compared with the pressure in the furnace.

2. By the action of the air, the surface of the molten iron becomes oxidized. In iron containing much carbon the oxygen is transferred from the air by means of the metallic surface to the carbon, which it oxidizes to carbon monoxide, which again bubbles up through the molten mass; hence it is in such irons that we find the greatest amount of blisters on the surface after cooling. White irons show fewer of these, and spiegeleisen solidifies with a smooth surface.

3. As the mould into which the molten iron is run always contains water, this water is vaporized by contact with the liquid iron, the steam thus generated is partly given off as gas, and partly decomposed, hydrogen being evolved and iron oxide being formed. Again, if the iron contains sulphur, this, by reacting on the steam, will form sulphuretted hydrogen, which is often formed in the cooled iron.—*A. Ledebur, Chem. Central, 1873.*

The Universal Diffusion of Heat the End of All Energy.

Professor Belfour Stewart recently delivered a very interesting lecture in Manchester, England, on the "Energies of Light and Heat." The lecturer explained the two great laws of thermodynamics, one of which, determining the quantity of mechanical energy necessary to produce one degree of heat, had been discovered by the eminent Mr. Joule, and the other, being the law according to which heat might be converted into work, the establishment of which law was greatly due to the labors of Sir William Thomson.

This latter law showed that no work could be obtained out of heat unless we had a fall of heat from a higher to a lower degree, just as we could get no work out of water unless it fell from a higher to a lower level. Upon this principle the uses of the boiler and condenser in a steam engine were explained, and in the work done by the globe, it was shown that the heat passed down a great boiler in the shape of the equator to condensers in the shape of the poles. Our winds were due to the passing, in obedience to this principle, of the heat from the equator to the poles. While all work, as in the boring of a cannon or in friction, could be changed into heat, all heat could not be changed into work. According to this principle of the universe, the universal diffusion of heat would ultimately be the fate of all energy.

While the principle of the conservation of energy was quite true, there was also another principle equally true called the dissipation of energy. That was, as it were, the great communist of the world. It tended to distribute itself equally in such a way that no work could be got out of it, and would ultimately bring the visible universe to an end, at least, so far as available energy was concerned. Heat denoted two kinds of energy, namely, absorbed heat and radiant light and heat. Hot bodies parted with their heat to cold bodies by three processes—conduction, convection and radiation.

COMBUSTION.—The heat produced in "slaking" lime is due to the intensity of the chemical action. It is in reality combustion. The lime has a strong affinity for water, and unites with it to form a hydrate. Chemical combination is regularly attended with the evolution of heat. This is illustrated in our ordinary methods of obtaining heat by the burning of fuel, which is simply a process of oxidation. If a piece of iron is ignited in a jar of oxygen gas, it burns quickly with a great heat. If the same piece of iron is allowed to rust away in the air, it is none the less burned, though slowly; and the whole amount of heat produced is precisely the same as in its quick combustion in oxygen gas.

DARWINISM.—There is one objection to Darwinism, says a late writer, to which little, if any, attention has been given: For example, the nearest creatures to man in form are not the nearest in intellect. The elephant, and dog and horse, which have no affinity to man have a far closer intellectual affinity than those pets of Darwinism, the gorilla and chimpanzee. Again, men is omnivorous—the stronger races of men, from the Greeks before Troy to the English of to-day, are primarily carnivorous. But no monkeys are carnivorous. If a man is to be developed from a lower creature, he is nearer to the monkey in form, but to his faithful friend the dog in mind.

deap mining in that district will pay. Rock which will pay \$180 per ton, and such as two men can take out at the rate of not less than one-half ton per day, is pretty good.

LONE STAR.—Ore from this mine is now being reduced at Carleton's mill. The immense body of good ore now opened, renders this the king mine of the district.

MADRA.—Henry & Son have a portion of their milling machinery running on rock taken from the mine—good ore too—while the balance of the reducing works are devoted to onstom services.

JOSEPHINE.—Operations are industriously prosecuted, and a good mine developing. Goldson and Herbert are taking out ore above the bottom of the shaft, and as soon as finished they will commence sinking. At the lowest depth attained, the ore "horas" an ounce to the osrgo.

EL DORADO.

FINE NOOCT.—*Mountain Democrat*, (Placerville), April 3: At the Granite Tunnel claim, Smith's Flat, Messrs. Partridge, Lucas & Co. last week took out a very handsome nugget of pure gold which weighs a fraction over eight ounces and may be seen in the show-window at the jewelry store of F. F. Barss. This oldsiu is being worked very systematically, and ever since it fell under the present management has been paying handsomely, the yield frequently including handsome specimens of coarse gold, though we believe the nugget above referred to is the largest they have yet obtained.

CINNABAR.—H. T. Turnbull was in town one day last week, having with him some very fine specimens of cinnabar which he reports to have been taken from the claim in which he is interested, located a few miles from Shingle Springs. These are not merely "tracings," they are the genuine article, and yield as high a percentage of quicksilver as any of the celebrated Napa discoveries. We also received, but have somehow mislaid, a communication from a correspondent located further toward the Amador claim than the location in which Mr. Turnbull is interested. This correspondent reported a four to six inch seam of very rich cinnabar, and very encouraging prospects for a valuable discovery. He also sent and criticized a notice from the *Amador Ledger*, in which, because of its name, the best development of cinnabar in that vicinity is claimed as in Amador county, while in fact it is considerably this side of the line between the two counties. All reports from that region count in sanguine confidence that a rich quicksilver district is in course of development.

FRESNO.

DISCOVERIES.—*Mariposa Gazette*, April 3: For some time past we have heard rumors of the discovery of a vein of gold-bearing quartz in Fresno county, near the boundary line of Mariposa county, some two or three miles below Crook's ranch, and near what is known as Indian Peak. The discoverers of this hoanza are J. Floyd Dodds, John Bye, Thomas Collins and James Lewis—most of whom were former residents of Mariposa county. They made the discovery some time in December last, since which time a shaft 6x8 feet has been sunk on one side of the vein to a depth of 30 ft. The vein is about 35 ft in width. The rock taken out was worked in an erastra, and yielded from \$275 to \$515 per ton. After about three months work, our informant says, the owners passed through Merced, on route for San Francisco, with the product of their labor, it being forty pounds and ten ounces of gold. It is said the parties have been offered from \$40,000 to \$100,000 for their mine.

INYO.

PANAMINT ITEMS.—*Inyo Independent*, April 3: We are indebted to Judge J. M. Murphy, Mining Recorder of Panamint, for the following interesting items:

There is a great excitement in Panamint over the discovery of an immense lode, called the Juno, of free milling ore, four miles south of Panamint city. The ledge is 40 feet wide, and from 40 assays made, the lowest went \$40 and the highest \$420. The fortunate discoverers are James A. Parker, James Bruce, C. D. Gill and Mr. Stinberger. It is at the Happy valley side of the mountain. The owners would not dispose of their interest for less than \$200,000.

The Stewart's Wonder mine, at a depth of 250 ft, struck an immense body of ore, the richest yet found in any of the company's mines.

The Jacobs mill is working successfully at concentrating. It is said that the tailings from ore running to \$150 will not assay more than \$6 per ton. This success in reducing ore insures a most prosperous future for the camp, for there is no lack of the ores, refractory as they may be.

The 20-stamp mill is rapidly approaching completion. An order arrived at Panamint, from the company, for the erection of a Stetefeldt furnace.

The tramway to the Wyoming mine is under way, and 50 more men were placed on the line to complete it as soon as possible.

Panamint is recovering from dull times, and inside of six weeks the Surprise V. M. & W. Co. will have in their employ not less than 500 men.

J. J. Dolan has been working the Jessie May lode, and now it takes rank with the Wyoming. Gen. Evans has a ruck 7 ft of ore in the Ocean Queen mine, and is about permanently locating in this country.

KERN.

DISCOVERY.—*Kern county Courier*, April 3:

We hear of an important mining discovery that has recently been made a few miles north of Kernville. For more than twelve years past prospectors have been in the habit of finding rich gold and silver-bearing float rock on an extensive flat near an affluent of Kern river, called Bull Run, but without meeting with success in their efforts to trace it up. This piece of good luck was reserved for John Dunn and Albert Bunnell. The ledge averages 15 ft in thickness, and has been traced upward of two miles. The specimen shown us is rich in free gold and chlorides and sulphurets of silver. Seven claims of 1500 ft each, besides those of the discoverers, have been located. It is in the same mineral belt—an upheaval of the primitive strata and igneous rocks—to which the Sumner mine, of Kernville, belongs, and that has been traced north and south nearly a hundred miles. The lead is called the "Albanel." An assay of the ore, made at Kernville, shows \$225.90 in gold, and \$143.35 in silver, or a total of \$369.25 to the ton.

NEVADA.

PITTSBURG MINE.—*Gross Valley Union*, April 1: The Pittsburgh mine, in the Deadman's Flat neighborhood, is sending out splendid ore from the shaft. The ledge is now from two and one-half to three feet in thickness, and shows well in metal, plenty of free gold being in the metal. The new hoisting and pumping works give entire satisfaction. The main shaft is now being put down in the direction of China.

EMPIRE MINE.—Yesterday two fine looking gold bricks were brought in from the Empire mine. They were the fres gold products, excluding sulphurets, of a four weeks' run. The two bars aggregated in value the sum of about \$22,000. This is very good for the oldest working mine in the district. We can remember that on several occasions the Empire managers, when things looked a little blue n' der ground, started in to pull up the pumps and to close down the mine. That was not done, however, and the Empire is now looking better than she ever did before in all her history.

DARTMOUTH MINE.—*Grass Valley Union*, April 4: We think that the Dartmouth mine, on the east part of the Alta hill, is doing pretty well; we can say excellently well. Yesterday a pan of dirt, from the north drift of the mine, was washed out by Captain Miller, the Superintendent. The dirt was not selected, although it was well known that the dirt in that part of the drift is very rich. The pan of gravel yielded the sum of \$25.25 in the prettiest washed gold we have seen since the days of the famous Alta company No. 2. The Dartmouth is doing well.

SIERRA.

STROCK GRAVEL.—*Mountain Messenger* (Downieville), April 3: Word comes to us that the South Fork company, at Forest City, have struck gravel that prospects, in their tunnel. The company raised a shaft about fifteen feet in their tunnel, strock gravel, and found the bed rock pitching. They will now run the tunnel ahead to strike the bottom of this lead. There was considerable excitement over the strike.

SONOMA.

QUICKSILVER ITEMS.—*Russian River Flag*, April 1: The Calistoga silver mine mill resumed work last Monday, with a full force of men.

The Sonoma furnace was lately fired up, and is now roasting good ore. The mine looks well. The Socrates has 23 men at work, and is getting out fifty tons of ore per day. The mine is in fine condition. A small bunch of retorts for testing ore is in operation. Geo. Maylone is superintendent.

T. B. Sleeper informs us that the New York, a mile and a half south-east of Pine Flat, is now being worked by four men. The main tunnel was in, last Friday, 240 feet. From the pitch of the ledge it is believed that the tunnel must run 60 feet further to reach the ore body. Fifteen tons of high grade ore have been taken from a face cut.

We believe the following to be a correct list of all the furnaces in this county:

Name of Company.	Pattern of Furnace.
Rattlesnake	Lockhardt
Scorpion	Lockhardt
Annie Belcher	Knox & Osborn
Geyser	Knox & Osborn
Ida Clayton and Yellow Jacket	Knox & Osborn
Excelsior	Winterburn
Livermore	—
Cloverdale	—
St. Jackson	Almaden

The Missouri & Oakland have retorts. In Lake county the Redington has Knox & Osborn furnaces; the Great Western, a Green and a Lockhardt; the Sulphur Banks, a Lockhardt and a Knox & Osborn.

The Live Oak mine, near Cloverdale, is working seven men (night and day shifts); the lower tunnel has advanced 370 feet, the last fifteen feet in ledge matter. The Ray tunnel is 205 feet long, with side drifts and a shaft.

TRINITY.

PROSPECTS IMPROVING.—*Trinity Journal*, April 3. Later developments in the Mountain Laurel cinnabar mine, on Canon creek, are favorable and indicate the existence of a large body of ore in that neighborhood. By way of experiment, 16 ounces of ore from the Mountain Laurel tunnel was reduced in a common gold retort and produced over 5½ ounces of quicksilver—about 35 per cent.

WILL BE WORKED.—Flowers & Lang will reopen and work the Wilt mine on Canon Creek. Although this claim did not pay last season, it is thought to contain some good ground.

CINNABAR.—Hawlett & Lytle are still getting out good ore in the Altona mine. The retorts will be fired up and the manufacture of quicksilver begin next week. The ore will be assorted at the mine and the best shipped to the retorts. A ditch is being dug from Crow creek to the Altona, the water to be used in concentrating the low grade ore. Several new cabins are being erected at the mines, and lively times are expected during the Summer.

TUOLUMNE.

CINNABAR.—*Tuolumne Independent*, April 3. Some little excitement has prevailed the past week in consequence of cinnabar ore being found on the east side of Tuolumne river, about a mile west of Madame Watts' house, on Marsh's Flat. The locations are in a belt of country bearing cinnabar, which was discovered high on the ridge, some 1,000 or 1,500 feet above the river. It is a serpentine rock, or rather vein matter, of greenish color, with strings of quartz, the whole being thickly stained with vermillion, the metallic luster showing plentifully therein. The original claim, the Great Eastern, relocated by W. G. Long, on the 16th ultmo, was partially prospected in 1862, quicksilver having been found in the gulch below. A tunnel 60 feet in length was run toward the vein, when a difference of opinion arising among the proprietors as to the mode of working, a general dissatisfaction ensued—a premature blast frightened the parties and put an end to the work and the claim was abandoned.

WORK BEGUN.—*Union Democrat*, April 3. A company of capitalists commenced work this week on the old Chandler and Beals claim, in the gravel range on the middle fork of the Tuolumne river, about 16 miles above Garrote. They recently bought the claim with an area of several hundred acres and will spare no effort to develop it. Men are being sent up and large orders for lumber have been given. If it proves to be profitable it will be the commencement of opening up a large extent of gravel mining.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—*Gold Hill News*, April 1: The face of the north drift to connect cross-cuts Nos. 1 and 2 on the 1500-ft level is still in rich ore. Cross-cut No. 3 east is also running in ore of the finest possible character. Cross-cut No. 4 on this level is making good headway, the face in good milling ore. Sinking the winze from the 1400 to connect with the 1500-ft level is making good progress, the bottom still in fine ore. The face of the east cross-cuts on both the 1400 and 1500-ft levels are still in ledge material of a favorable character. Sinking the C & C shaft is making rapid progress. Repairing and retimbering the main north drift on the 1550-ft level is about completed.

OPHIO.—The ore breasts on the 1465-ft level are all looking well and yielding the usual amount of ore. Daily yield 150 tons of ore. Sinking the northeast winze on the 1465-ft level, is making good headway, the bottom still in ore. The face of the northeast drift at the 1600 ft station, in the north winze, is still in fine ore. Cross-cutting on the 1700-ft level is still vigorously prosecuted, with some favorable indications of better ore developments to the eastward.

JULIA.—The face of the main south drift on the 1000 ft level is still in vein material of a fine encouraging character. The flow of water from the face continues about the same.

SILVER HILL.—The prospecting drifts north on the third station level continue to show improvement as the work progresses. Work on the new machinery is progressing finely.

CONSOLIDATED VIRGINIA.—Daily yield 460 tons of ore, keeping the mills steadily running. The ore breasts on the 1300 and 1400-ft levels are looking splendidly and yielding the usual amount of rich ore. The east cross cut on the California line on the 1400-ft level is in 184 feet, the face still in quartz and porphyry mixed. The north drift on the 1300-ft level, to connect with the east cross-cut on the California line, will have about 50 feet yet to run to reach the point at which it is expected that the two drifts will meet.

JUSTICE.—Owing to the very hard rock met with at the bottom of the main incline, below the 800-ft level, sinking continues to be slow. The south drift at the 800-ft level is now in 65 feet from the incline, with the face still in hard vein material and very wet. Burchleigh drifts are soon to be brought to bear in both incline and drift.

CALIFORNIA.—Sinking the main incline shaft at the old works is making excellent progress. The main incline is now down 110 feet. Sinking the new shaft is making splendid progress, it being necessary to put in a set of timbers almost every day. It is now down 67 feet, the bottom in excellent working ground. The new hoisting engine is working splendidly.

SAVAGE.—The south drift from the 2200-ft station of the main incline has completed a connection with the north drift from the south winze, thus securing a splendid circulation of pure air, cooling off the level and greatly facilitating the prospecting in that portion of the mine. The main drifts on that level are now being enlarged and car tracks laid, preparatory to cross-cutting the ore vein.

SIERRA NEVADA.—Sinking the old shaft is making excellent headway, the rock in the bottom working quite soft. Driving the north-east drift on the 700-ft level of this shaft is making fine progress.

LEO.—This ground in the face of the main tunnel is working better again. The ledge matter is getting softer and shows improvement in character. Good headway continues to be made in driving the northeast drift, fine buncbes and stringers of ore being met with daily.

UTAH.—There is little or no change in the flow of water at the bottom of the shaft. Prospecting, both north and south, on the 400-ft level, still continues, with no material change to report except a strong increase in the flow of water from the face of the north drift.

CROLIAR-POTOSI.—The main south drift on the 1150-ft level, during the week, cut some favorable looking quartz, with seams of clay interspersed, but has not yet found anything of value, the highest assays obtained being \$2 to \$3 per ton.

YELLOW JACKET.—The 1840-ft level is still flooded with water, and all work suspended in that portion of the mine for the present.

BULLION.—The prospects of finding pay ore on the 800-ft level is looking more favorable than at anytime in the past. On the 1700-ft level of the Imperial a cross-cut has been started 100 feet north of the south line, which is now passing through the mixed vein matter on the west side of the ledge.

AMERICAN FLAT.—The prospects on the 750 and 850-ft levels for valuable developments are steadily on the increase, and now that the new pumping and hoisting machinery is about completed, are being looked forward to with a great amount of interest and confidence. As soon as the pumping machinery has been thoroughly tried the development of the lower levels will be commenced in good earnest.

BALTIMORE CONSOLIDATED.—The new pumping machinery will be in good condition to commence draining the lower levels of the mine by Monday next, everything, so far as tested, working with the utmost perfection. Once the machinery is all in good running order, work at all points in the mine will be resumed, when some valuable ore developments are confidently expected.

NIAORA.—An average assay of the ore in the bottom of the shaft, yesterday, gave a result of \$14.13 in silver and \$87.89 in gold, making a total of \$102.02. The arrival of the new hoisting works machinery is expected daily.

PHIL SHERIDAN.—More stringers of quartz of a reddish brown character have been passed through since last week's report, and these increase in size and favorable appearance as the drift progresses.

OVERMAN.—The 1100-ft level has been reached by the incline, and a drift started east to connect with the main west drift from the shaft on the same level.

ROCK ISLAND.—The shaft is down to the 450-ft level, at which point a station is being opened for the purpose of cutting and prospecting the ore vein.

GOULD & CURRY.—The enlargement of the main shaft to the fourth station level was completed yesterday, and the putting in of the new pumping machinery is making all the speed possible. Nothing is doing on the 1700-ft level, owing to the strong flow of water.

CROWN POINT.—Daily yield, 550 tons of ore. The ore breasts on the old upper levels are all looking well, and promise a goodly yield for many weeks yet to come. Prospecting on the 1600-ft level is still carried forward with all the energy possible. Work progressing well at the 1700-ft station.

WOONVILLE.—All work in the mine is suspended for the present, with the exception of driving the north drift and sinking the south winze below the 300-ft level. Sinking the new shaft is progressing finely. It is now down 215 feet.

LADY BRYAN.—Sinking the winzes in the ore body below the 80-ft level is making good progress, the bottom still in fine milling ore. Driving the main south drift on the same level is still continued, the face also in good ore. A west cross-cut has been started on the 180-ft level, which is now in a distance of 24 ft, in a fine body of whitish blue quartz, containing spots of rich ore. The main west drift on the 250-ft level is still driven vigorously ahead, through a fine body of favorable looking quartz and low grade ore.

KOSUTH.—The south drift from the main west cross-cut, on the 350 ft level, is in a distance of 60 feet in as fine a ledge as is to be found on the line of the Comstock. The ore vein is much better defined and more promising than it was on the lower levels above.

FLORINA.—The foundation work for the heavy new machinery is going ahead as expeditiously as possible.

ORIGINAL GOLD HILL.—From the main south drift the cross-cut has run into the continuation of the excellent ore body found in the upper above that level, and it is found to be of the same good quality.

DAYTON.—The erection of the new pumping machinery is making excellent speed. Sinking the main shaft is making rapid headway, with strong indications of soon cutting the main ledge.

BUCKEYE.—The water is again drained, and good work is being done opening the 550-foot station. The prospects of finding pay ore on this level are very favorable.

IOWA.—Preparations for the erection of the new hoisting machinery are making good progress.

NEVADA.—Cross-cutting now in the ledge, from the tunnel, to see what good ore developments can be discovered at the lower level. Prospects excellent.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Tenth Lecture Delivered before the University of California College of Agriculture, on Monday, February 1st, by Prof. C. E. BAKER.

The Nightshade, Star Apple, Tobacco, Etc.

The nightshade family, *Solanaceae*, are herbaceous or woody plants; in all about 1,000 species, of these a very few species are found all over the world, but the most of the species are tropical, so that speaking of it generally we must call it a tropical order. Although some when prepared are wholesome, yet the whole family is more or less poisonous and this poison is a narcotic. Several plants, however, are of the greatest value for food and, outside of the order of *gramineae*, I doubt whether there is another single plant which has as much general value as the potato, *Solanum tuberosum*, a native of the higher regions of South America and also found to a certain extent in Mexico and one very nearly allied species is found growing in portions of California. The potato was originally very small, but culture has changed it. In this change, it seems as if the size of the potato was increased, while the amount of poisonous matter in it was not increased, so that it is considerably diffused and probably this is due largely to culture. It was first introduced into England in 1597, by Sir Walter Raleigh; but for fully a century it was very little esteemed. In fact, only within the last hundred years, it has come into general use. Not only does it furnish food, but it furnishes starch for use in the arts. From it also there is produced, in some parts of the country, a spirituous liquor somewhat resembling brandy. I should say, whenever these tubers are exposed to the sun, they are

Pervaded by This Narcotic Poison;

So, of course, it is unhealthful to make use of them.

The egg plant, *Solanum melongena* is another South American plant. [Fig. 1.] It bears large egg-shaped fruits which are used in cooking. It has never come into general use. Further, it has so much of this poisonous matter that unless taken at the proper time there is danger in it.

The tomato, *Lycopersicon esculentum*, also from South America, is now largely grown for its delicious fruits, though for many years after its introduction it was supposed to be poisonous and was grown only for ornament under the name of love apple. Almost any of the old people will tell you of seeing it grown years ago just for an ornament. Now, in these the poison is still present when they are green, but in ripening the sun seems to eliminate the poison from them. If eaten when they are green they are injurious, unless prepared in vinegar or in some manner so as to remove the unwholesome tendency. [A student. "The sun seems to have an opposite effect upon them from that it has upon potatoes."] [Professor explained this, saying]—When the sun shines upon a potato, it changes the tuber into a stem, and it is therefore poisonous. I suppose if the fruit of the potato when ripe could be eaten we would find little poison in it. As long as the fruit is green there is a great deal of poison in it which can only be dissipated by the sun or the heat of cooking.

Another plant is the ground cherry or cherry tomato. It belongs to the genus *Physalis*, and is a little, low plant, with yellow, or orange-colored fruit, not unpleasant to the taste, enclosed in the enlarged calyx. It grows in the United States. The winter cherry, *Physalis alkekengi*, is a native of Southern Europe; now considerably grown for ornament.

Cayenne pepper is the product of *Capsicum annuum*, a South Asiatic plant, coming from India, now largely grown in all warm climates. In this case the narcotic matter or poison seems to be changed into this pungent matter found in pepper. What we call Cayenne pepper is the variety which grows large, long pods. These being annuals, of course can be grown very far north, and can also be grown well to the south.

Stramonium, or thorn apple—you see we are passing from the food plants to the medicinal ones—*Datura Stramonium*, is a large ill-scented weed, with very large, trumpet-shaped flowers and prickly pods. Its seeds [Fig. 2], contain an alkaline principle considered valuable in medicine. When taken in considerable quantity they produce raving and in excess profound stupor. Stramonium is kept in the shops in considerable quantities. It is said to be one of the ingredients of

Drugged Liquors.

When any one is put into a stupor through taking certain liquors, generally stramonium has been used in the liquor. It is, however, used quite considerably in legitimate practice.

Belladonna is a product which has a better reputation and is derived from the perennial herb, *Atropa belladonna*, a native of Europe. The whole plant in this case is exceedingly poisonous, and from it we get the drug known as belladonna. Like henbane, which is derived from a nearly allied species, it has the power of dilating the pupil of the eye. If a drop is allowed to fall upon the eye, upon the pupil, it will

dilate greatly and it is from this fact it gets its common name.

[Belladonna is derived from two Italian words *bella*, beautiful and *donna*, lady; according to Webster.]

The Spanish and Mexican ladies have long made use of this to try to lighten the beauty of their eyes. Our oculists now put it to a better use.

Tobacco, *Nicotiana Tabacum*, is a native of the warm portions of America. [Fig. 3.] It was used by the original inhabitants of this continent long before the Europeans came here, but it was very soon introduced into Europe. In 1589, Sir Walter Raleigh took the tobacco to England and some eight years afterwards the potato also. At first, it met with great opposition, throughout all Europe; kings, priests, popes, everybody opposed it; nevertheless, its use spread rapidly over all the countries of the civilized world. Some of the authorities say that on an average

Every Fourth Man

Makes use of tobacco. A greater part of the product is derived from the United States. There is a strip of country including Virginia, Ohio, Pennsylvania and running down into New England, also including portions of Tennessee, Indiana, Illinois and southern Iowa—all through that belt of country is a very important district engaged in tobacco growing. Certain varieties are grown very far north. I have known its very profitable cultivation up

Fig. 1. Seed Pod of Thorn Apple—*(Datura Stramonium)*.

near Lake Erie. It probably will become of more and more importance.

Among the weeds we name black nightshade, which is a remarkable plant botanically, from the fact that it is found running as far north as a plant will grow, up into the frozen regions; and also in the southern temperate zone, it extends as far as plants will grow. This is an anomalous case, because as a general thing the plants of the north temperate zone are hardly found in the south temperate zone at all. Second, the "jimson weed" or thorn apple. It grows abundantly in almost all cultivated places. It grows in California. Both of these weeds are poisonous.

Among the flowering plants only one is worth mentioning, and that is petunia. This, within the last six or seven years has been considerably improved, although a few years ago it was called old-fashioned. Its ease of growth and delightful fragrance place it very deservedly quite high among the ornamental plants.

Referring again to tobacco, I just want to make one remark: You will find the statement frequently in our agricultural journals that tobacco is not an American plant. I think that remark comes from this: there are a great

Fig. 2. Egg Plant.

many species of *Nicotiana*, some of which are not native of America, and I think it is from this we get the statement that the Chinese were acquainted with tobacco long ago. The tobacco largely used all over the world for smoking and chewing is an American plant.

The second order, the

Mints

Of the order *Labiatae*, are herbs or small shrubs, never trees; mostly with square stems, very abundantly distributed, but most abundant in the temperate zone. There are upwards of 2500 species, throughout nearly all of which is to be found a highly aromatic and pungent property which has caused them to be long held in high repute as possessing medicinal virtues. At the present time this medicinal use has nearly passed away, and they are restricted almost entirely to a few strong scent d plants which make up the medicines of quacks and herb doctors. In fact, this order furnishes the perfume or odor for the quack medicines more than any other we have. A few, how-

ever, are harmless plants, used in domestic practice, and called, generally, herbs. This aromatic principle is of importance as furnishing some very useful oils and essences.

First, is lavender, from the *Lavandula vera*, which is a little shrubby plant found in South Europe, grown for its leaves; from these by distillation is obtained oil of lavender. This, dissolved in alcohol and mixed with water is what is known as lavender water, and is used largely in perfumery.

Rosemary, (*Rosemarinus officinalis*), also a shrubby plant found in Southern Europe, and to some extent in Western Asia; is grown for its oil, used in the manufacture of all sorts of perfumes; also very largely used in the manufacture of cologne water—one of the more important ingredients in the latter.

There are a great many others. I simply will mention a half dozen or more of them in testimony of this fact, that the order is an order of perfume. Peppermint, pennyroyal and sage are European; sweet basil is from India; hor-hound and catnip are European. You can hardly mention a plant of this order but that it is more or less aromatic.

Some of these, as peppermint and pennyroyal, are used in domestic practice. It is my opinion that they are quite harmless, but as to their real virtues, I don't whether they possess any. If we must take something whenever we have a little pain, I suppose we might as well take these. I do not want to put myself on record as against taking medicine when pre-

Fig. 3. Tobacco Plant.

scribed by a physician. If we wish to dose ourselves, without knowing anything about their properties, these things may be taken.

A few plants of the order are of ornamental value. Two are in quite common use—*Coleus* and *Perilla*; these are the generic names. They run off into false species or varieties. These, here, have a brilliant, red color. They grow erect, in hot-houses; here, out of doors. Sage, an Indian species, and oestropetal, are grown for ornamental purposes. When these three are mentioned, you have about all. It seems a little strange that an order of so many species should not furnish more, more valuable for ornament. None furnish food for man or beast, though a few are used as substitutes for tea, very poor at that. None furnish textile materials or materials which can be used in any way in building—no woods.

There are but few bad weeds. I do not call to mind a single one but that can be readily driven out. As soon as you use the plow or hoe they disappear. It is possible that in some localities there are some of more weedy habits. The group may be considered as yielding medicines of a poor order, and perfume of a high order; and it illustrates perfectly how one predominant character may determine the position of an order or group in the list of economic plants. The aromatic property which it possesses determines its position.

Next we take up several small groups of but few species, but of considerable importance, and first is the

Ebony Family,

Ebenaceae, a small group of only a hundred and sixty species; found chiefly in the tropics. It derives its name from the ebony tree of the East Indies, and of the surrounding countries there. The Ceylon ebony, *Diospyros Ebenum*, is from Ceylon. A second one, *D. Ebenaster*, is from India, as is also *D. melanocylon*. *D. reticulata* is from the island of Mauritius. The tree is large, and very slow in their growth, as you will expect from the nature of the wood. In the largest, the wood is of a light color, but after a while it begins to turn dark, and takes on the very dark, almost black, color to which it has given a name. This is labeled here as a true ebony. I have some very grave doubts whether it is, but then it will show you, however, what ebony is—its general appearance. I think if a bit of that specimen was taken out and boiled in water a coloring matter might come out. It is probably white-wood stained and

Sold as True Ebony.

The true ebony should not have the appearance which you will see if you hold it up to the light in the proper way. True ebony blackens in the center, and from the center outward. It is, therefore, difficult to account for any such whitening on the inside. Then again, it is not hard enough. True ebony should be jet black, considerably hard and quite brittle. The best is that coming from Mauritius. Ceylon and India are not so valuable.

There are a few allied species which furnish some woods of a good deal of value in certain

localities, but so far, their values are only local. In China and Japan, one of the species of this same genus *Diospyros*, furnishes a very valuable and very delicious fruit. It is called there the *Kaki*, or Chinese date (*Diospyros Kaki*), and so in giving it a name, botanists very wisely gave it the same specific name which it has for a common name. You understand that it is not the date spoken of in literature generally; but this is a fruit about the size of an apple, said to be exceedingly delicious. It is eaten from the tree and also preserved—makes a sort of fig-like preserve. Can be

Grown in Southern California.

If not already introduced, it could very profitably be brought into the United States.

In the eastern United States and running up, I hardly know how far, into the Rocky Mountains, we have what may be called the American date, or the American date palm.

It is known in the East and, probably all over the country, as the Persimmon, *Diospyros Virginiana*; the American date palm, or Persimmon, is a tree growing from twenty to sixty feet high. It produces a plum-like fruit, which, when green, is exceedingly pungent. When ripe it is sweet and edible. Now, from the fact that this closely allied species produces such a very delicious fruit, and a hardy one too, it is very likely that this same Persimmon, if taken into nurseries and cared for, might, in a short time, be developed into a very good fruit indeed; notwithstanding that the same Persimmon is one we almost always smile at, as not worth thinking much of. It abounds through almost all of what might be called the interior States, including Ohio, Indiana, Illinois and southward. There are some in this extreme southern portion of Iowa. I think there is no part of Southern California as cold as Southern Iowa. However, as this *Kaki* could be grown in the southern part of California, there is no need of introducing it, the Persimmon, there. Taking it wild, we, of course, expect it to be a poor thing; but grow it, selecting the best varieties wherever it sports, and no doubt in a very short time we might get from it valuable fruit.

The Star Apples

Form softer small order, the order *Sapotaceae*, which includes about two hundred species, mostly tropical, and they are all either shrubs or trees. Throughout the whole order, the plants are possessed of a milky juice, and this upon drying becomes more or less glue-like. In gutta percha, or, the gutta percha tree, this becomes of very great economic importance. The gutta percha tree, *Isopandra gutta*, is a tree from sixty to seventy feet in height, found in Southern Asia, and on the islands of Borneo and others near by. The juice is secured by cutting the trees. The natives there seem not to know how to get the juice in any other way. They cut the tree and peel off the bark and by so doing obtain the juice, but this results in rapid destruction of forests. As the juice dries, it is made up into little cakes and is exported. When brought to the United States, or England, or any of the countries on the continent, it is manufactured into all sorts of utensils and is applied to a great variety of uses. As the trees only produce from twenty to thirty pounds apiece and as the consumption requires a very large quantity annually, there is great danger that it will become extinct. No steps have been taken, except by the British government within the last few years, for the purpose of replanting these trees, and as the policy adopted by the natives is suicidal, we ought to be looking out for something to take its place. Its uses are very many. One peculiarity it has, is that when heated it softens up and can be molded into various forms and when it cools becomes hard and retains its form; so it can be very largely used for any purposes required. Then again, it is used for the telegraph cables. Very likely, if gutta percha had not been found just when it was

Should Not Have Had Atlantic Cables.

At least, for some time yet. In order to prevent the great waste resulting from the present method, the trees could be tapped or partially girdled and their juice thus utilized for six, seven or eight successive years. This method, though not giving so large immediate results as cutting down the trees, would give a larger aggregate.

Now, Europeans pay no attention how the natives get the material together at the seaports. In some species, this milk is used for food by the natives. I suppose in such species the juice does not coagulate or dry up as soon, and in some cases the juice is used just as the natives of South America use that of the cow tree, and as the Pacific islanders have always used that same tree.

The star apple and the sappedilla plum, of the West Indies, are large trees bearing delicious fruits about the size of an apple, which are said to be second only to oranges. Here, we know nothing at all about them. In fact I never saw a star apple or sappedilla plum. They are difficult of transportation. They could be grown, almost to a certainty, in certain parts of this State. A few species furnish valuable woods, but they are not of general importance as yet, being known only in certain restricted districts, so we pass them by.

SPONTANEOUS COMBUSTIBILITY OF CHARCOAL.—Andrew F. Haller says: Charcoal absorbs its maximum amount of oxygen from the atmosphere within three days after carbonization and that after that time no danger need be apprehended in using it, while up to that time its use may be attended with danger.

GOOD HEALTH.

Washing the Inside of the Body.

There is no cavity in the body which water is not fitted for if you get it in properly. Why, one of the best things you can do is to wash your blood, and the great folly we commit in going through our lives from childhood to the grave, is that we do not wash our blood as we ought. Infusions of coffee, tea, chocolate, or cocoa, or elder, or beer, do not wash the blood, because, with the fluid so taken in, something is carried in also which befouls and defiles the blood. Let a man say to himself, "It is Saturday night; I have worked hard all the week, and Sunday shall be a day of rest to me. I am going to give my whole system, between this and Monday morning, a good, thorough washing." So he begins to drink, and drink, and drinks but little at a time, yet between Saturday night and next Monday morning, a healthy man can drink without producing any disturbance a gallon of water. Now let this come into and go through his circulation—through his lungs, and skin, and kidneys, and bowels—and waste materials are carried out; and when Monday morning comes, if he jumps out of bed and gives his external skin a good washing, the water that he washes in will be foul. Or, if he prefers to test the question even more thoroughly, all he has to do is to take a clean sheet, and then wetting it in good, soft, pure water, he wrapped up in it for forty-eight or sixty minutes, and then have the sheet washed in a tub of water, and it will color that water so it will look dirty. The man has been washed inside—his blood has been washed. When you have washed his blood, tissues, bones, nerve, muscle, sinew, membrane, and brain, and everything in him, he can defy all pestilence for that week. The washing of a person's outside is twice as necessary as the washing of a person's clothes, yet there are those who are very particular to have their clothes washed, who seldom take a bath.

DOGS AS PROPAGATORS OF DISEASE.—Among the many agents for the spread of infectious diseases, are, it seems, "our domestic pets." For the propagation of fever a dog is sometimes as bad, or worse, than a drain; and a case is referred to in the *Sanitary Record*, in which scarlet fever was carried from one child to another by a favorite retriever. The dog had been reared in a house where scarlatina prevailed, and was subsequently given to a friend of the family. Shortly after, one of the children in the dog's new home was attacked with malignant scarlatina, and died. Disinfectants were used plentifully, and every precaution taken to prevent a recurrence of the malady, but in two months' time a second child took the same disease, in its worst form, and died. As the dog had been the constant companion and playfellow of these children, its woolly coat, it is alleged, became so charged with contagious matter as to render it a source of disease and death. Although it is only fair to the dog to admit that the children may have caught the fever from other sources than his woolly coat, yet there is reason to fear that both dogs and cats, especially the latter, do exist in the circulation of infectious illnesses; and where fever prevails the sooner they are lodged out of the house the better. They are, however, probably not more dangerous in this respect, than books. No one who takes up a book from a library ever troubles himself or herself as to the antecedents of the volume; it may have just left the hands of the fever patient.—*Pall Mall Gazette*.

AIR REQUIRED FOR RESPIRATION.—The average amount of air inspired and exhaled at each respiration is 30 cubic inches, and the average number of respirations 20 per minute, so that 500 cubic feet of air pass through the lungs in 24 hours. The amount of carbonic acid exhaled is variable, and is interesting as an index of the rate of internal change. The more energetic the circulation, the larger the quantity of carbonic acid; it is less during sleep than when awake, and less during fasting than after a full meal. A sleeping apartment should always have adequate ventilation while in use.

DUST-SPECTACLES FOR THE PROTECTION OF THE EYES IN VARIOUS OCCUPATIONS.—Spectacle-frames, furnished with fine wire gauze instead of glass, carefully fitted to the eye, and fastened to the head by a gum band, have been found by Kuhn to answer perfectly for the protection of the eyes from dust, solid particles, &c., in various occupations, as threshing, stone-cutting, &c., while they, at the same time, permit the necessary access of air to the eye, and produce no inconvenience whatever to the wearer.

HEALTHY OLD AGE.—The brains of people advanced in years would be greatly strengthened by habits of study. Old people should have their lessons, their mental culture, like children, to keep their brain in a healthy condition. Moderate study is almost a sure guarantee against decaying of the mind as age advances.

QUICK RELIEF FOR BURNS.—Apply a layer of common salt, and saturate it with lanolin. Hold it in position a few hours with a simple wrapper. The colonel says the smarting disappears almost immediately, and the sore gets well with incredible rapidity.

TO DETECT BRIGHT'S DISEASE.—Urine when mixed with nitric acid and boiled should coagulate if the person is suffering from Bright's disease of the kidneys.

When to Get Up.

The Duke of Wellington always slept on an iron camp bedstead eighteen inches wide. "When a man wants to turn over," he said, "it is time for him to turn out." The Emperor Nicholas did the same, Mr. Owen says. The principle is well enough; but I think the detail is wrong. Sleep is far too important to be made uncomfortable. My old friend Rossiter fixed his alarm so that, at the fore-dawned moment, the bed clothes were dragged from the bed, and Rossiter lay shivering. I have myself somewhere the drawings and specifications for a patent (which I never applied for), which arranges a set of canvas and wheel-work under the bedstead, which, at the moment appointed, lift the pillow-end six feet, and deliver the sleeper on his feet on the now horizontal foot-board. He is not apt to sleep long after that.

Rossiter found another contrivance which worked better. The alarm clock struck a mitch, which lighted the lamp, which boiled the water for Rossiter's shaving. If Rossiter staid in bed too long, the water boiled over upon his razor, and clean shirt, and the prayer book his mother gave him, and Coleridge's autograph, and his open pocket-book, and all the other precious things he could put in a basin underneath when he went to bed; so he had to get up before that moment came.—*Old and New*.

USEFUL INFORMATION.

Wheeled Vehicles.

The history of locomotion on wheels is one which takes us back to the very origin of all history. The horse was undoubtedly the animal whose labor was first utilized by man; but no doubt he was employed many centuries before the wheel was known as a vehicle of locomotion or transportation. Carrying loads was the first occupation of this useful animal; next he was probably employed as the Indians on this continent still use him, to drag loads or poles—one end of said poles being secured to the flanks of the animal, while the other rested upon the ground, the load being placed near the middle.

The next idea was to rest the ground end of the poles on wheels, from which the transition to the two-wheeled cart and the ancient chariot was a very natural step. No doubt the ancient Egyptians and Assyrians were content, for many ages, to travel upon two wheels; yet it was an inevitable necessity—that a four-wheeled vehicle should ultimately have been suggested. In the first attempt to build such a vehicle, the second axle was no doubt fixed to the body rigidly, in the same way as the single axle had been. The inconveniences attending the working of such a rigid four-wheeler, and its obstinate tendency to move in a straight line, no doubt condemned the early wheelwright to much mortification and disgust, and his contemporary Jehu must often have heaped anathemas on his head in the vain efforts to gracefully turn the corners of the gay avenues of their city drives. No doubt such disgust led for a time to the utter condemnation of the new-fangled vehicle and a return to the use of the more easily managed two-wheeled chariot.

But necessity was then, as now, the mother of invention, and the perch-bolt must have been soon devised, as the only means of making a four-wheeled vehicle a really practical thing on a common road. Once introduced it was sure to survive, and the carriage-maker of to-day who should propose anything for an substitute would be considered a fit candidate for an insane asylum. The railway car-builder, however, has gone back to the original construction. His practically straight road allowing the possibility of such a device. But this is only another case of history repeating itself. The modern iron road being entirely novel in its design implies a similar novelty in all its appurtenances. But the car-builder of a century hence will wonder that such a barbarous running gear could have been endured on a railway in 1875. The audible grinding of a rail road train on a short curve, and the wear and loss of power consequent upon the wheels being dragged out of their natural curve, assure us that we have not yet reached perfection in railroad gear. The perch-bolt or its equivalent must be eventually employed upon the iron as well as on the common road, and that, too, without sacrificing the steadiness of the vehicle or any other essential condition of safety and comfort.

THE EXCLUSION OF DAMP FROM BRICK-WORK. It is stated that one of the most effective methods of accomplishing this object is the following:

Three quarters of a pound of mottled soap are dissolved in one gallon of boiling water, and the hot solution spread steadily with a flat brush over the outer surfaces of the brickwork, care being taken that it does not lather; this is allowed to dry for twenty-four hours, when a solution formed of a quarter of a pound of alum dissolved in two gallons of water, is applied in a similar manner over the coating of soap. The soap and alum form an insoluble varnish, which the rain is unable to penetrate, and this cause of dampness is thus said to be effectually removed. The operation should be performed in dry, settled weather.

Another method is to use eight parts of linseed oil and one part of sulphur, heated together to 278° in an iron vessel.—*Scientific American*.

The Omnibus Not a New Invention.

The omnibus is not, as is generally supposed, a modern device. Its history is traced back to the year 1662, when Louis XIV. authorized a line of them for the special benefit of the middle classes. Seven omnibuses were started, each constructed to hold eight people. The terms of concession to the company provided that they should run at fixed hours, whether full or empty, to and from different quarters of the city, for the benefit of the infirm and those engaged in lawsuits, as well as for all who could not afford to hire a carriage. But before long the new conveyances were converted from their original purpose and became extremely fashionable. The Grand Monarque traveled in one to St. Germain, and his example being followed by the aristocracy generally, the class for whose benefit they had been introduced were completely excluded. This fashionable whim appears, however, to have lasted only a short time, followed by the failure of the company, owing to the subsequent refusal of the poorer classes to patronize the new vehicles.

Nothing more was seen of omnibuses in the French capital until 1828, when they were again introduced by a leading banker, who made a large fortune out of the speculation. It was not until two years after this date that they made their first appearance in the London streets, when two were started by an enterprising citizen, running between the Bank and the western extremity of the New-road. These ponderous vehicles carried twenty-two passengers inside. But in some respects they appear to have been superior to the modern omnibuses. The first conductors were sons of gentlemen, and the periodicals of the day were provided gratis, by the proprietors, for passengers to read en route.

Restoring Burnt Iron.

Many are the ideas that have been presented toward the above end, but so far, we believe, nowhere is the method carried on extensively. Many establishments that accidentally or otherwise meet with such incidental loss contrive to work off the iron so burnt by a proportionate mixture of new iron, and perhaps some use certain chemicals. But to restore burnt iron in large quantities by any systematic method we do not know to be followed. Such material we know to be a common product incident to the manufacture and working of iron; sufficiently great in quantity to justify special facilities for its redemption, but beyond the small efforts of those who meet with such loss in a comparatively limited way, no well-directed and special method toward making it a business has been done.

Quite large quantities of burnt metal are to be found at various foundries, which is not wholly "slag," as many suppose, left from the "charge" of a foundry air furnace or cupola, but in the majority of cases is burnt metal. One of our city founders pointed to a lot of several tons as "burnt iron, not slag." In our mills a common way of disposing of burnt wrought iron is to work it off in small quantities with new iron; either with scrap or by re-piling with puddle bar.—*American Manufacturer*.

A THREE-WHEELED OMNIBUS.—The *Carriage Builders' Gazette* furnishes an illustrated description of quite a novelty for the road, in the shape of a three-wheeled omnibus. It is claimed that by this construction, economy in cost and draft, as well as comfort for riders is secured. Dispensing with a truck or under-carriage and one wheel, admits of economy in construction; while the triadic bearing of the wheels on the ground favors the draft. The bulk of the load is placed upon the pair of wheels, which are large and forward, and is partly suspended beneath the line of the axle. The axle of the single wheel is in the rear of the body of the vehicle. There is an entrance, placed diagonally upon each rear corner, which may be reached more readily than the rear entrance of the omnibus as commonly constructed. A stairway also leads to the roof of the vehicle from the rear. The total weight of an omnibus, as ordinarily constructed, to accommodate 28 passengers, ranges from 20 to 24 hundred-weight. A three-wheeled vehicle to accommodate the same number can be constructed to weigh from 14 to 16 hundred-weight only. The construction is very simple—the hind wheel turns freely in an upright axle-box, filled with a coil spring around the spindle. The body forward rests upon elliptic springs.

THE LIFE OF LOCOMOTIVE WHEELS.—It is seen by the returns of the London and North-western (Eng.) Railway, made to Parliament in the year of 1873, that their locomotives average a run of about 15,000 miles a year, and that the usual term of service of a set of chilled wheels is about seven years,—or a run of 105,000 miles,—a little more than four times round the world. Passenger cars traverse about three times the distance each month or year that an engine does. First-class cars are not subjected to such continuous wear as inferior ones; more rest is given to the wheels. Such cars are heavier, and consequently bear harder on the axles, and hence are more liable to heat.

CAR WHEELS.—A St. Louis company are producing car wheels with steel tires, which are said to be as much superior to iron wheels as steel rails are to iron rails. The distance an ordinary wheel will run is said to be about 50,000 miles, while it is claimed for the steel tired wheel that it will have a life of about 400,000 miles.

DOMESTIC ECONOMY.

How to Roast Beef.

Somebody recently sent a receipt to the *Ohio Farmer* for roasting a sirloin of beef. Another correspondent—"An Old Housekeeper," takes correspondent No. 1 to do after the following manner: "The receipt furnished by your correspondent of the 9th instant, for roasting a sirloin of beef, is not the way that I or any experienced housekeeper would attempt to cook it. It first recommends a 'joint weighing from fourteen to fifteen pounds from a young and fat beef.' Now, everybody knowing anything about good beef would say, 'old and fat beef.' Young beef is neither so tender, juicy or rich as old beef, as the fat and the other flesh on the latter is newly put on. The writer goes on: 'having laid it in the dripping pan, tenderloin downward, we dredge it slightly with flour.' Doesn't this writer know that all 'doctoring' of beef helps to deteriorate its quality? To go on, the meat is then put down in the pan, in which a little water is poured, and then put in the oven, not to roast, but to stew. The writer then adds: 'As soon as the surface of the meat is so browned that the juices of the meat will not readily escape, allow the oven to cool to a moderate degree of heat.' This is remarkable. 'When the beef is done, sprinkle with salt and pepper. Empty the pan of all its drippings; pour in some boiling water, slightly salted, stir it about and strain over the meat.'

"This is one way, truly, and it may suit some people who have never eaten really good roast beef; but it will not do for me or my family. Why, beef, to roast it in the best manner, should not be tampered with in any way—not even touched with water before putting in the oven. Instead of laying it broadside in the water of the pan, it should be elevated on a 'meat stand' placed in the pan. A quarter of an hour to a pound of beef is the correct period to roast. No dredging, peppering, salting or pouring over of gravy, etc.; they destroy the sweetness, deliciousness and relishment of the beef."

English Dishes.

"An English Woman" furnishes the *German-town Telegraph* with the following recipes for preparing certain English dishes:—

BULLOCK'S LIVER.—Cut the liver in scores, and salt it with two pounds of salt for a fortnight, then let it drain dry for three days, then rub in two ounces of several kinds of spice, according to your judgment, and all sorts of sweet herbs chopped very fine; also a good seasoning of onions and shallots. Then hang it in a dry cellar for a time, and then put it in a bag for use. A small piece is sufficient to make gravy for hares, ducks, &c. It will keep many months, and be useful to use in the summer.

FRI-CASSEEN TRIPE.—Cleanse tripe well from the fat, cut it into pieces about two inches broad and four long, put it into a stew-pan and cover with milk and water; let it boil till tender. Slice two Spanish onions and put in a stew-pan with a quarter pound of butter; salt, pepper and nutmeg to flavor, and let them brown; put this sauce with the tripe, add the juice of a lemon, and serve very hot.

YORKSHIRE PARKIN.—Two and a half pounds of oatmeal, two pounds of treacle, a quarter of a pound of moist sugar, half a pound of butter rubbed into the oatmeal—a little ginger or finely cut candied peel may be added if liked; mix all well together, put into tea-cake tins, and bake.

WINTER SALAD.—Boil some potatoes and some onions, and when cold cut them into slices, together with some beetroot. Dress as any other salad. The onions should be cut so as to fall apart in rigs.

To Mend Tinware.

Every housekeeper may not know of what they are capable in the line of keeping their tinware in order. For the benefit of such we will say that it is easier to solder such things than to pay a traveling tinker two prices for mending them. Take a sharp knife and scrape the tin around the leak until it is bright, so that the solder will stick. Then sprinkle on a little powdered resin, (they have liquid solder to sell, but resin will do as well), lay your solder on the hole, and with your solder-iron melt it on. Do not have the iron too hot or the solder will adhere to that. After two or three trials you can do a job that you will be proud of. If you do not own a soldering iron procure one by all means; but when hard pressed I have used the knob on the end of the fire-shovel, or a smooth piece of iron, or held a candle under the spot to be mended. Anything is better than stopping leaking pans with beeswax or rags. Try it, young housekeepers, and see how independent you will feel. Your pans should be dry when you take them in hand.

RICE JELLY.—Boil one pound of flour with half a pound of loaf sugar in a quart of water until the whole becomes a glutinous mass, strain off the jelly and let it stand to cool. This is nutritious and light.

CANDY.—Two cupfuls of sugar, two large tablespoonfuls of vinegar, and half a cupful of water. Boil together, and add vanilla or lemon for flavor. It must be worked before it is very cold.

Working Gold, 234.

Society of Engineers of California.

A meeting of this society was held on Monday last. Mr. G. W. Dickie in the chair. Papers presented by W. J. Lewis, C. E., "On Calculation of Earthworks," and by W. W. Hanscom, M. E., "On the Screw Propeller." The paper of the former gentleman was altogether too technical to be of general interest, and was drawn out to too great length. We might suggest a conformity to the customs of similar societies elsewhere, on the matter of papers of this character. They are simply interesting as matters of reference to those pursuing that branch of the profession to which the paper relates and should be submitted by title and referred to the publication committee. Even those to whom the paper is valuable would prefer to have it in print where they could refer to it at leisure. But when the author thinks proper to read the paper he should at least carefully arrange his manuscript, models, etc., in such a manner as to have everything in proper order before he goes on the platform; otherwise the audience are under the necessity, as was the case in this instance, of impatiently waiting every now and then for five minutes or so to elapse, while the reader was trying to find the right page. In the present case brevity is a valuable adjunct to a paper and the more condensed the information the more chance there is of its being read or listened to.

The paper on the Screw Propeller, by Mr. Hanscom, was brief and pithy, and advanced some new views, to which others in the profession take exception. Owing to the lateness of the hour, discussion on the paper was postponed, although Mr. Dickie, of the Risdon Works, appeared anxious to give his reasons for dissenting with Mr. Hanscom's views. The paper will be discussed at the next meeting of the society, and as the members will have time to post themselves on the subject, a lively and interesting discussion may be expected. Mr. Hanscom's paper will appear in our next issue.

ALL of the mills in Six and Seven Mile canyons are running to their full capacity.

Watchmaking in San Francisco.

Watchmaking has now become a prominent manufacturing industry in San Francisco. The large building recently fitted up on Fourth street for the Cornell Watch Manufacturing Company is now quite well filled with machinery. Something over one hundred operators—about one-quarter of whom are females—find constant employment there. Still the works are not yet in full and complete operation. Their completeness requires time, and it is really wonderful to see what has been done in so short a time as has elapsed since the project was first set on foot.

When the project of starting this factory was first broached, the idea was received by the public with many misgivings. But the skill and enterprise of the founders and experts, and the public spirit of several of our prominent capitalists has brought the scheme into full realization, with a resolution and dispatch which is highly creditable to their spirit and energy, and we have no doubt that it will also meet with the full financial success which it so richly deserves.

The officers of the company are as follows: Paul Cornell, President; Oliver Eldridge, Vice-President; Bank of California, Treasurer; H. Cox, D. D., Secretary; Charles R. Bacon, Superintendent. Directors, John Parrott, Peter Donohue, William Norris, Paul Cornell and Oliver Eldridge. It would be difficult to combine a better or more substantial set of men for the head of such an establishment in this or any other city.

A Visit to the Factory.

We took occasion, a few days since, to visit this interesting scene of industry. We found Superintendent Bacon—who is evidently the right man in the right place—at his post, and, on making known to him the object of our visit, he very politely and kindly invited us to a thorough examination, and offered to accompany us through the various departments.

The building is a three-story brick, and well adapted to the purpose. Everything appears to be in perfect order and admirably arranged for the purposes in view. To describe all we saw would be a task which we are not prepared to undertake—in fact, such a description could not be prepared from the observations of a single visit.

The Machine Shop

Was the first room visited, and, as the foundation of all, is located upon the ground floor. This department is under the special supervision of Mr. G. S. Kendrick, master mechanic, who has had many years' experience in designing and constructing machinery of this description, and is thoroughly competent to fill so important a position. A large portion of the machinery was brought from Chicago, where, it will be recollected, the factory was first started, and removed here mainly on account of the superior fitness of our climate for such delicate workmanship. It is the policy of the company to manufacture their own machinery, tools, implements, etc., which is nearly all of such a delicate and peculiar character as to necessarily involve the closest personal inspection of the experts of the factory itself. The motive power is also placed in this room, and consists of a steam engine of 15-horse power.

The Various Departments

Are mostly confined to separate rooms—the rooms being so arranged as to secure the fullest advantage of sunlight—for which purpose the building is admirably located. The departments are fifteen in number, divided and named as follows:

The machine shop, the pattern room, the draughting room, the plate room, the pinion-forwarding room, pinion finisher, the escapement department, flat steel and screw department, the motion department, the balance department, the jeweling, the gilding, the dial, finishing and the case departments. The latter is quite separate from the others, being, in fact, a business or department of itself. Both silver and gold cases are manufactured here, of various styles and prices. In addition to the various departments there is also the

The Material Room.

The latter is near the center of the building on the second floor, and is in charge of a lady, who receives and hands out all the fine stock and material which passes into any of the departments, or from one department to another. By this system every item of material, finished or unfinished, is carefully accounted for, and can be readily followed by those in charge from day to day; and from one department to another. This is the center and heart of the whole establishment, from and to which everything flows in continually recurring currents.

Both key and stem-winders are turned out by the Cornell company. The latter though simple in construction, nevertheless require more labor in their manufacture than the former. Their great convenience, however, makes them especially desirable, particularly for the ladies. Among the various kinds of delicate workmanship to which our attention was called, was that of a lady who was provided with machinery and tools to drill holes one eighteen-thousandths of an inch in diameter—to our eyes, at least, absolutely microscopic in size.

The pinion department is very interesting for its minuteness, and it is upon the perfect execution of this work that the excellence of the watch largely depends. The pinions are turned out of the best steel wire. About one

hundred pieces are made from a piece of wire about a foot long, in an almost incredible short space of time, and with a precision which is absolutely astonishing. These pinions work in jewel sockets, which last have also to be adjusted with the greatest nicety and exactness.

Among the minutiae of the various portions of the watch, we were shown a small box containing what appeared to the eye to be small granules or particles of iron. A magnifying glass was subsequently placed in our hands, by the aid of which we were enabled to perceive that we were examining a lot of most perfectly finished screws, so infinitesimally fine that it requires nearly 190,000 to make a pound troy! We were informed that some of the pieces that go to make up a watch were subjected to 20 distinct operations before they were ready to be put in place.

The balance department interested us much, not on account of its minuteness, of course, but on account of the great care taken in its construction to render that important piece of mechanism as far removed as possible from the evil effects of expansion and contraction by change of temperature. In most watches but a single metal is used in the construction of the balance-wheel; hence variations of temperature cause much inequality in such time-pieces. All the Cornell watches are provided with balance-wheels consisting of two metals—steel and brass—so peculiarly and carefully combined as to reduce their possible variation in size to the minimum quantity.

And right here we may stop to remark a noticeable and important feature in all the watches turned out at this establishment, and that is the rapidity of the balance-wheel movement. A slow motion is much more largely affected by jars than a quick movement. This is an important consideration in these days of railroad travel. It is impossible for a slow movement to be kept regular on a railroad car, and proportionally so under any other condition of travel or constant concussion.

A watch is rated at this establishment chiefly by the value and perfection of its movements, which vary in price from \$16 to about \$150. Any desired class of movements can be placed in any style of case, silver or gold.

As a Home Institution

The Cornell watch factory may now be referred to with pride. Its future will no doubt be grand and important. It will in time become the most successful and extensive establishment of the kind in the world. There are several reasons for this conclusion, which any intelligent person cannot fail to foresee. Watchmaking is a business which from the delicacy of its manipulations requires a mild and uniform temperature. The extremes of heat or cold are equally injurious to its successful prosecution. There is not another locality in the world which so well meets these conditions as San Francisco. The company starts as a progressive institution. It has fitted up its own machine shop, which it proposes to continue in constant operation, adding to and increasing its power for turning out work as fast as the growing market for its productions shall demand.

The factory is located directly at the gateway of the great Pacific ocean, through which the travel of its islands and hording continents must continue to move with constantly increasing volume, until this city shall become the great commercial center of the world. New York has nearly reached the climax of its possibilities—henceforth it must surely divide its growth with its sisters on the seaboard and in the interior. London and other great cities of Europe are much in the same condition. Climate is against them, the tide of travel and of empire is against them all, as compared with San Francisco, the population of which is doubling with every decade. Our industrial enterprises and institutions are also bound to keep full pace with our growth. Our mines and our enterprise makes that a fact beyond doubt. Japan and China are just opening up an immense market for watches and a large line of other industrial products, and is building up a current of travel which will soon convert our semi-monthly steamers into a daily ferry line across the Pacific. The chief part of the industrial supplies for these peoples must reach them from this city.

When American Watches

Were first talked of, very few people believed in them. It was thought that the skill which two or three centuries had given to European operatives would have to be of similar slow growth here—especially as this considered certain when our capitalists were unable to buy foreign machinery at any price or induce for eign laborers to come here to any extent. It was probably well that we were thrown upon our own resources. The Yankee never does better than when he is reduced to just that extremity. That was his opportunity in the watch business, and he went to work in his own way, invented machinery after his own ideas, and can now discount, by large odds, the best machinery and the best workmanship which Europe can produce. The American watch, and watch manufacture is to-day as far in advance of that of Europe as is our skill in the manufacture of the revolver or the sewing machine. And so it will ever be with any class of instruments which are made by what is technically called "assembling"—when any part of one machine is made to answer the same purpose in any other machine of the same pattern and size. This is, as it ever will be, the result of the superiority of machine work over hand labor, which last enters into every department of construction, much more largely in Europe than here.

But we have extended this article altogether beyond the limits intended, and that too, we fear, without giving our readers what they probably expected at the outset—something of a mechanical idea of what a watch factory is. The fact is, we found there was too much to learn and describe in a single visit, and if the patience of Superintendent Bacon and our readers both hold out, we propose to repeat our visit at some future time, and so inform ourselves as to be able to tell more of what the Cornell watch factory really is—leaving its future to its own practical demonstration. Mr. Cornell is determined to make the enterprise a success in every particular. By the partiality of his associates, his name has been indissolubly connected with its existence, and he is resolved to make the institution his life's monument.

A Disastrous Explosion.

A fearful explosion of Giant Powder occurred on Hathaway's wharf, at Rincon Point, on Wednesday afternoon, by which several lives were lost and a large amount of property was destroyed. About 150 pounds of Giant Powder had been brought from the factory in the morning, for blasting operations in removing Rincon Rock, in the bay, and this powder caused the explosion which resulted in such loss of life and property. The rock is very near the wharves, and Clark, the foreman, went to the office on shore to prepare the cartridges for a blast. While doing this the explosion took place.

The most probable reason for the explosion is given in the following statement by George Green, a blacksmith who worked on the rock:

I went into Risdon's office with Mr. Clark and Joe Corran to have a talk. I used to work for Mr. Risdon. Mr. Clark went into the office to get the cartridges ready for blasting. He took the loose powder out of a box filled with powder and put this powder into tin cans with a wooden scoop through a hole about one and a half inches large. He had filled one can and placed it on the table and placed two empty cans near the box and commenced filling them. The box with powder was standing on the floor from which he filled the cans. He then lighted his pipe and sat down on an empty box alongside the powder. He was crossing his legs which jarred his pipe in his mouth, from which dropped some fire into the box of powder. He then tried to extinguish this spark of fire with his finger pressing on it, when after a moment the powder in the box blazed up, on seeing this I ran out to a distance of about 50 feet, when I heard an explosion take place.

He had a number of fuses prepared with the caps on the end of them. These were some three or four feet from the can of powder on the table. There were two more cases of powder in the room; also, two small tin boxes, which I think contained caps, standing on the table. There were also some paper cartridges, with powder, in a box in the room.

I only saw one can filled and two commenced on, but I do not know if there were other cans filled or not.

Exactly how the explosion took place will never be known but this statement is probably nearly the truth. Still, in all probability, some of the cans on the table had the fuses on them or the caps and fuses were nearer the powder than Green thought, and their discharge fired the powder. The Giant Powder company have made experiments in this direction and find that by firing 100 caps within six inches of a box of powder it would explode; but a foot and a half away it would not. These experiments have been numerous and exhaustive, and with 100 caps each time. When the powder which caught from the spark of the pipe blazed up it probably set off the fuse and caps and discharged one can of powder, which in turn set off the rest. With such a blaze as so much powder would make, the fuse might be easily fired close to the lower edge and discharge the caps and powder. People smoking pipes around powder might expect accidents and it shows Clark's confidence in it that he should do so. Black powder under such conditions would not have allowed Green to get away but would have exploded, not burned. Clark has been handling this powder for some years and was probably careless with it. Corran, his assistant, may have also prepared other cans or cartridges, which exploded at the same time. Fuses with caps prepared, boxes of open powder on the table and floor, and a lighted pipe were good materials for an accident and this was a fearful one.

Hathaway's large bonded warehouse was destroyed with its contents, as were also a number of smaller buildings. The loss of property tops up about \$600,000. The killed were Frederick Hasse, James McIntyre, Clark, Brown and Jesse Langdon, and a boy of the injured will probably die. Besides those injured by the explosion, numbering ten, four firemen were badly hurt; one having his leg broken, another his shoulder and knee dislocated, another his arms and ribs fractured, and the other badly burned. The firemen will probably recover. But Richard Richard, B. Thompson and Wm. Knight, of the wounded, are not expected to live. The accident was a most awful and fatal one, and should warn others not to be careless with dangerous explosives. If the burning powder had been thrown into the street before it ignited the fuse and exploded the other cans no harm would have ensued; but in such cases people almost always lose their presence of mind.

Reduction of Quicksilver Ores—Patera's Process.

There is, perhaps, no other ore, the reduction of which is attended with such a proportionate loss, as ore containing quicksilver. Patera, in describing his new method for the reduction of cinnabar ore states that in Idria (Austria), the loss of quicksilver used to amount to from 46 to 48 per cent. in the reverberatory furnaces, 59 to 74 in the shaft furnaces, and 7 to 9 per cent. in retorts. He explains the causes of this great loss as follows:

1. The ore is fed into the reverberatory furnaces as coarse sand and in small pieces; into the shaft furnaces in larger and even very large pieces. There remains, therefore, in the furnaces some of the cinnabar which is not properly roasted.
2. The temperature applied is always very high, and in consequence the quicksilver fumes become very much expanded, and are therefore difficult to condense.
3. The temperature and draft in the reverberatory and shaft furnaces cannot be properly regulated; and an excess of atmospheric air with the products of combustion of the fuel and carbonic acid of the ore, mixed with the already much expanded quicksilver fumes, pass through the condensers, preventing, to a great extent, the condensation of the fumes.
4. The porous masonry-work of the reverberatory and shaft furnaces absorbs much of the quicksilver, which can only be recovered when the furnace is torn down.
5. The above conditions demand very large condensing chambers, which again entail considerable loss.

Having ascertained the causes of loss, the remedy can be found according to Patera, as follows:

1. Reduce the ore into smaller particles.
2. Select a furnace which allows the regulation of the temperature and the admission of air, and
3. In which the products of combustion have not to pass through the condensers.
4. The furnace selected should not absorb any quicksilver fumes, and then
5. We shall not have any necessity for such a large and complicated condensing apparatus.

On these principles Patera has devised his process, and constructed the furnace with which he made his first experiments, and which is shown in the accompanying engravings.

The furnace A (Fig. 8) contained a cast iron tube $2\frac{1}{2}$ inches in diameter and $1\frac{1}{2}$ feet long. It was open at a and was connected at b with a glass tube of equal diameter and two feet long. Then followed several Wolf's apparatuses (which need no detailed description) and last came an exchanger, E, which drew the air slowly through the whole apparatus. About three inches from the furnace a thermometer, t, inserted in a glass tube, to observe the temperature during the whole operation; on several other parts of the apparatus were other thermometers for the same purpose. The first experiment was to ascertain how small the ore pieces have to be, so that the ore will be completely roasted, or all the quicksilver expelled at a low temperature. To this end samples of ore of different sizes, which contained from one to two per cent., were heated moderately in a porcelain cup, so that the cup did not get red hot. After two hours heating the ore was pulverized in an agate mortar, and assayed.

The most suitable size for the ore is that of pretty fine grains of sand, because after one hour's heating, no more trace of quicksilver could be found. The ore reduced to this size was put in the pipe or sheet iron saucers; the temperature was kept low, say from 400° to

500° C., so that the pipe did not get red hot. The thermometer three inches from the furnace rose from 70° to 80° , and here occurred the greatest condensation; at the end of the tube less was noticed. The thermometers at the other parts of the apparatus did not indicate any rise in temperature. It sometimes happened, particularly in treating rich ores, that small quantities of fumes passed in an op-

low temperature. It is easily kept tight, and the draft is easily produced by connecting the outlet of the condensing apparatus with the fireplace, and regulating it by valves or dampers. Patera was unable to introduce his process until he himself constructed a furnace made like the one shown in the engraving.

The apparatus represented by Figures 1 to 7 consists in a cast iron retort, M, with condens-

ranged in the usual way, as can be seen from the drawings.

The front of the retort is closed by an iron cover, which has two openings, a, a, one inch in diameter, from which lead iron pipes which admit air and allow the operator to look inside during the operation. To protect the laborers from the fumes which might escape through these openings, a hose, b, is attached to the end of the iron pipe, which leads into an open vessel, c, wherein the escaping quicksilver may be collected. This vessel may be of iron, or of brick and cement, whichever is most convenient.

At the back end of the retort, at c, the first condensing pipe is attached. It has there exactly the same incline as the retort, but towards c the bottom forms a kind of trough, slanting towards c'. At the deepest point is a pipe for the outlet of the quicksilver, and opposite is another one, to admit of the first being cleaned. The condensing pipe is closed by a cover, which has two openings; the one E is two inches in diameter and leads to the other condensing apparatus; the other opening is closed, as it is only a spare one. In the top of the condensing pipe is a hole, T, for a thermometer, by which the temperature of the passing fumes can be noticed. At E the connection with the other condensing apparatus is made. This consists in a system of clay pipes, of two inches in diameter, which terminate, finally, in the fire-place. At several points in the system of pipes, holes are provided, which can be closed, so that the operator can see whether complete condensation has taken place.

To effect a rapid condensation the pipes ought to be large and kept cool by water; by means of a partition the fumes are compelled to pass close to the side of the condenser, which produces, also, a very good effect. The thermometer, T, at the condenser near the retort, showed a temperature from 210° to 230° C, whereas, it showed at the other end, say about three feet distant, hardly 30° . The length of the first large condensing pipe for different sized furnaces is somewhat difficult to determine. For Patera's experimental furnace the pipe was four feet long, and he found, at the end of the operation, most of the quicksilver in the part near the retort. He therefore thinks it advantageous to contract the condensing pipe suddenly after the first wide one. It is difficult to determine the length of this part of the condensing apparatus. In working 100 pounds of ore of 1.50 to 3.06 per cent., he had a condenser nine feet long, and found that considerable fumes passed in the fire-place. He then lengthened the apparatus to 12, and finally to 24 feet, and could find only small traces of quicksilver where the fumes passed into the fire place.

The manufacture of such small clay pipes is not difficult. Patera considers sheet iron the best material for the first large condensing pipe; further on, clay pipes are preferable. The whole operation takes about two hours, and at the beginning the fires should be very slow. The residue of ore of 3.06 per cent. contained .05 per cent., and the pure quicksilver amounted to from 88 to 90 per cent. The sheet iron condensing pipe is coated inside with "hartenlack" (a hard varnish), and outside with platinum paint.

The advantages claimed for this process are: the greater percentage obtained; the purity of the product; and prevention of the formation of soot.

AN IMMENSE FLUME.

The Fresno lumber and flume company, in Fresno county, are constructing under the supervision of George H. Perrin a flume which when completed will be fifty-four miles in length and is what is known as a V flume. It will be thirty-eight inches across the top. It starts near the Fresno Big Trees and will end at some point on the Southern Pacific railroad. It is intended to carry sugar-pine lumber to the railroad from the mills of the company. Twenty-four miles of this flume are already completed. The entire cost of this flume will be near \$250,000.

posite direction to the current of air out at the end, a, of the pipe, when the temperature rose. To prevent this and to protect the laborer, the pipe was closed at a, and a pipe applied to the middle of the cover. With this apparatus the ores were tested as to quantity. In this manner Patera got 85.07 of the quicksilver contained in 2.08 per cent. ore; in richer ore he got from 91 to 94 per cent.; the quicksilver contained very little soot.

Encouraged by the results of these experiments, Patera obtained a patent in 1871. The furnace is a very simple one, on account of the

ing apparatus. The bottom of the retort is two feet wide; it is nine inches high, and ten feet long; three inches of each side rest on the brick wall, and three inches project beyond the rear wall, to connect with the condensing apparatus. Therefore, it gives four square feet heating surface of the retort bottom, available for the spreading of the ore to be retorted.

As 100 pounds of quicksilver ore of two to three per cent., and reduced to that fineness, occupy one cubic foot, there may be spread 100 pounds of ore on the heating surface in a layer three inches thick. The furnace is ur-

CENTENNIAL PACKING. SELF-LUBRICATING.

FOR

Locomotive
Marine and
Stationary
ENGINES.

FOR

Steam Pumps
AND
Hot or Cold
Water Pumps
OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. ENGINEERS, TRY IT. For sale in any quantity by

DURVEA'S SATIN GLOSS STARCH AND DURVEA'S IMPROVED CORN STARCH

Are the Best in the World.

USE IT ONCE AND YOU WILL USE NO OTHER.

For Sale by All Grocers.

FAC-SIMILES OF PRIZE MEDALS AWARDED THE

The Messrs. Durvea have succeeded in refining Starch to entire purity and developing its entire strength and clearness, an improvement that will be readily perceived in the great strength of the Starch the superior luster that it gives, and in its reliable uniformity. Much of the so-called starch contains from one-fourth to one-third foreign matter, readily perceived by sourness, mustiness, or a golden yellow tinge, peculiar to inferior starches, a color not desirable for one's linen, but inseparable from the use of common starch. They pledge themselves to the public to give a uniformly superior article, from one-fourth to one-third stronger than any other starch in this world, and at the common market rates.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Super. of Quartz Mills and Mining Men generally:
We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburg Manufacturers
have been compelled to add largely in their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce SHOES AND DIES superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent. cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered.
Sizing iron under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the
mills on the Pacific Coast, and all who have tried them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness on first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amalgam
by absence of iron dross and chippings, and a saving of
75 per cent. in freight. It takes 60 days to fill orders
from the manufacturing East. Price 16 cents per
pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
1729-3m

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM
Awarded by the Mechanics' Institute Fair, San Fran-
cisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers
to be superior to any they have ever used; feed con-
stantly by pressure of condensed water, supplied by
pipe A, regulated under the oil by valve J, and forced
out through check valve and pipe I into the steam pipe
C; it then becomes greasy steam, passes to all the
valves and cylinder at every stroke of the engine; glass
tube I indicates amount used per hour. Packing on
rods and stems lasts longer, and the rings on the piston
will not corrode. One pint of oil will last from three
to six days, according to speed and size of engine; I,
sliding gauge; K, valve to shut off when engine stops;
H, F, valves to shut off in case of frost; stem does not
enter the cup; it is always cool; warranted to give satis-
faction. Patented February 14, 1871. Manufactured by
California Brass Works, 125 First Street, S. F. 24v23

TEATS'S PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing
and Oxidizing Ores, etc. For the reduction of
Gold, Silver, Lead and other ores, saving a larger per-
centage, at less cost, than any other invention now in
use. Chloridizing Silver ore more thoroughly, in less
time, with less fuel, salt and labor, also roasting Lead
ore preparatory to smelting, better and cheaper than
any other invention. The Furnace is so constructed
that one man, of ordinary ability, tends five or more
furnaces; controls them with ease; adding heat or air,
stopping or starting at will; charging and discharging
with ease. Also, Patent "Conveying Cooler," for con-
veying and cooling roasted ores, heating the water for
amalgamation and the boilers at the same time. Saving
the large space in mill covered with brick or iron,
and the labor of two men per day, exposed to the poi-
sonous chlorine gases. Also, Patent Air Blast "Dry
Kiln," for drying ores direct from the mine or breaker,
saving fuel and labor heretofore necessary in drying
ores for dry pulverizing. For description refer to
MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874.
For particulars address

D. B. MILLER & CO.,
No. 12 West Eighth Street, Cincinnati, Ohio
Circulars, &c., will be furnished, if required.
18v23-3m

CROCKER'S PATENT TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron
frame, five steel arms with stamps weighing 17 lbs. each,
which strike 2,500 blows per minute, in a mortar provided
with screens on both sides, and crushes 500 lbs. per
hour, requiring one-horse power to drive it. Has been
thoroughly tested, and is guaranteed to give good satis-
faction. PRICE, \$500.
G. D. CROCKER,
17v26-tf 815 California Street, San Francisco.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they
have no equal. No effort has been, or will be spared
to have them constructed in the most perfect manner
and of the great number now in operation, not one has
ever required repairs. The constant and increasing de-
mand for them is sufficient evidence of their merits.
They are constructed so to apply the stamp directly
into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pen being filled, the motion of the muller forces
the pulp to the center, where it is drawn down through
the aperture and between the grinding surfaces.—
Thence it is thrown to the periphery into the quicksilver.
The curved plates again draw it to the center, where it
passes down, and to the circumference as before. Thus
it is constantly passing regular flow between the grind-
ing surfaces and into the quicksilver, until the ore is
reduced to an impalpable powder, and the metal amal-
gamated.

Setters made on the same principle excel all others.
They bring the pulp so constantly and perfectly in con-
tact with quicksilver, that the particles are rapidly and
completely absorbed.

Mill-men are invited to examine these pans and set-
ters for themselves, at the office, 229 Fremont Street,
San Francisco

OAKLAND REAL ESTATE.—No city in this State equals Oakland in its general improvements and rapid growth. The building of the State University upon its very border, the large court house for Alameda county, several large and new churches, together with the \$200,000 appropriation by the Government for the improvement of its inland channels, stimulates great confidence in the future of San Francisco a sister across the bay. Oakland may well be proud of her public and private educational institutions. Its population is, in a great measure at least, now composed largely of people who choose a quiet home rather than the clatter and bustle of a great city. It has more advantages than we can stop to name, and people in the mines and agricultural districts are constantly investing in real estate in Oakland and vicinity for present and prospective homes. We think men are prone to make less wise investments. Parties who wish to post themselves further on the future prospects of Oakland, and to learn of the best chances offering for the sale of lots in Oakland and land in Alameda county, are confidently referred to the advertisement of Messrs. Bigelow & Rowell in the RURAL PRESS. These gentlemen, long residents of Oakland, are among its most enterprising and respected citizens.

WATER PIPE.—The necessity, in many sections of the State, for utilizing the water supply in the most economical manner, causes the demand for water pipe to increase with the development of our agricultural and mineral resources. While the mild and equable character of the climate renders the expensive and laborious method of laying pipe needed to guard against the severe winters of the Eastern States unnecessary here, the wants of the agriculturalist and miner have made it highly profitable to them to make use of this means for conveying water from the base of supply to points where it is required for use. So general has this now become that there is hardly a farmer but uses more or less water pipe, while in the mining districts miles of iron tubing conduct the reserved floods of the mountain streams to aid man in unveiling earth's hidden wealth. Prominent among the different qualities of pipe in this market is that of the Graff Tube Works, at Pittsburgh, Pa. The pipe of this company has achieved an excellent reputation, and loses nothing by being offered to the public through the agency of Mr. James L. Barker, 406 and 408 Market street. The grades most in demand on this coast vary from 1/2 inch to four inches in diameter and weigh from .42 to 18.77 pounds per foot. Mr. Barker keeps a large quantity of wrought and galvanized pipe of these dimensions in stock, and offers it at prices which compare favorably with those of other dealers.

General News Items.

A FEW days ago, in Gilroy, Mrs. Anna Bahh's little boy, three years old, drank a pound of quicksilver, which he found in a bottle in an old trunk, while playing. A physician was sent for, who administered some light remedy. The child gave no other indication of having taken the mercury than drowsiness. The metal did not leave the stomach for ten days.

A WRITER in the Visalia Delta states that Tulare lake contains twice the area usually ascribed to it, its length being seventy-five miles and breadth thirty miles.

A MARE belonging to Asa Butler, of San Benito, California, gave birth, a few days since, to two colts, one having five legs and the other but three.

THE San Diego World has changed hands. It still remains Democratic in politics.

THE waste dump of the Virginia City coal company, in El Dorado canyon, is on fire, and has been burning for about three days. It is supposed that it took fire from clinders thrown out from under the grates of the engine furnace. The dump is composed of a mixture of coal and dirt. The fire burns in a smoldering way and can do no damage, as the dump is at a distance from where the vein crops out.

A NEW double working shaft has been started in the Carolina mine, 150 feet east of the old prospecting shaft. The mine is 850 feet east of the Wells-Fargo, on the Comstock. The ledge is from 40 to 50 feet wide, and assays average from \$15 to \$20 in silver and gold—about two-thirds in silver.

A SUFFOCATING COUGH.

In a letter from Mrs. Charlotte Lisle, of Chicago, a lady well known as a contributor to the Western press, she ascribes the cure of a dangerous cough, accompanied by bleeding at the lungs, to HALE'S HONEY OF HOREHOUND AND TAR. "My cough," she says, "threatened to suffocate me * * * * * but the HONEY OF HOREHOUND AND TAR has removed every trace of it." The letter was to a lady friend in this city, who has placed it at the disposal of C. N. CRITTENTON, 7 Sixth avenue. PINK'S TOOTH-ACHE DROPS—Cure in one minute.

SANTA CLARA, CAL., April 6th, 1878.

MESSEHS. DEWEY & Co.—Gents:—We have just received Patent No. 160,535, for J. T. Watkins & Co's Mammoth Road Grader, which was patented through your Agency. It is the nearest and best that we have ever received. We feel proud of it and thankful to you for the care and attention that you have given it, and when we have anything to do in that line of business we will surely give you a call. Very respectfully, J. T. WATKINS & Co.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Galleries, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

GEORGE WILSON, formerly contributor of the MINING AND SCIENTIFIC PRESS, will please address this office.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & Co., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch. Dated Washington, D. C., April 6, 1878.

FOR WEEK ENDING MARCH 23.

TOOL FOR TURNING METAL.—Chas. Cummings, Virginia City, Nev.

BED-BUG TRAP.—John L. Hawkins, San Quentin, Cal.

WAGON-BRAKE BLOCK.—William Hendrick, Modesto, Cal.

WATER-WHEEL AND HYDRAULIC GOVERNOR.—Frederick G. Hesae, Oakland, Cal.

HYDRAULIC ENGINE.—William L. Smith, S. F., Cal.

VACUUM RELIEF VALVE FOR WATER PIPES.—Philip Hinkle, S. F., Cal.

GRAIN SEPARATOR.—Michael O'Brien, S. F., Cal.

AMALGAMATOR.—John Rutherford, S. F., Cal.

FRUIT JAR.—Pierre F. Darche, S. F., Cal.

DEMIOHON CASE.—Carlton Newman, S. F., Cal.

BAND SAWING MACHINE.—Olpha Bonnsy, S. F., Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

The Hull & Eelden Company, Danbury, Ct.

This is a Surs Cure for Scraw Worm, Scab and Foot Rot in Sheep. It also kills Ticks, Lice, and all Parasites that infest Sheep. Prevents scratching and greatly improves the quality of the wool. One gallon of this Dip properly diluted with water will be sufficient to dip one hundred sheep, so that the cost of dipping is a mere trifle, and sheep owners will find that they are amply repaid by the improved health of their flocks. This Dip is guaranteed to cure when used according to directions, and to be vastly superior to Corrosive Sublimates, Sulphur, Tobacco, and other remedies which have heretofore been used by farmers. Circulars sent, post paid, upon application, giving full directions for its use, also certificates of prominent sheep growers who have used large quantities of the Dip, and pronounce it the most effective and reliable known Cure and Preventive of Scab and other kindred diseases in Sheep. mrl3-bp

THE DR. BLY ARTIFICIAL LIMBS

166 Tehama Street,

COR. OF THIRD, BETWEEN HOWARD & FOLSOM

References to parties wearing these Limbs given when applied for.

THE "ANATOMICAL LEG" WITH A UNIVERSAL ankle motion; the above cut is its illustration. This artificial leg approaches so much nearer an imitation of the functions of nature than any other, that it stands without a rival among all the inventions in artificial legs, old or new. (The very latest announced new inventions duly considered.) Address MENZO SPRING, 166 Tehama Street, S. F., Cal. 6v30-lam-hp-3m

Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.

This compound of the vegetable alternatives, Sarsaparilla, Dock, Stillinger, and Mandrake with the Iodide of Potassium and Iron makes a most effective cure of a series of complaints which are very prevalent and afflicting. It purifies the blood, purges out the lurking humors in the system, that undermine health and settle into troublesome disorders. Eruptions of the skin are the appearance on the surface of humors that should be expelled from the blood. Internal derangements are the determination of these same humors to some internal organ, or organs, whose action derange, and whose substance they disease and destroy. AYER'S SARSAPARILLA expels these humors from the blood. When they are gone, the disorders they produce disappear, such as Ulcerations of the Liver, Stomach, Kidneys, Lungs, Eruptions and Eruptive Diseases of the Skin, St. Anthony's Fire, Rose or Erysipelas, Pimples, Pustules, Blotches, Boils, Tumors, Tetters and Sal Rheum, Scald Head, Ringworm, Ulcers and Sores, Rheumatism, Neuralgia, Pain in the Bones, Side and Head, Female Weakness, Sterility, Leucorrhoea arising from internal ulceration and uterine disease, Dropsy, Dyspepsia, Emaciation and General Debility. With their departure health returns.

And in accordance with law, and an order of the Board of Directors, made on the 15th day of February, 1875, so many shares of each parcel of said stock as may be necessary will be sold at public auction at the salesrooms of Maurice Dore & Co., No 326 Pine Street, San Francisco, on the 12th day of April, 1875, at the hour of 12 o'clock, m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale. A. B. PAUL, Secy.
Office, No. 318 California street, San Francisco, Cal. (Room No. 13.)
Gold Mountain Mining Company.—Principal place of business, San Francisco, Location of works, Lower Rancheria, Amador county, Cal.
Notice is hereby given that at a meeting of the Board of Directors, held on the 26th day of March, 1875, an assessment of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, No 118 Leidesdorff street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the 24th day of April, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
AUG. KNAPP, Secretary.
Office, 115 Leidesdorff street, San Francisco, Cal.
Keystone Quartz Mining Company.—Principal place of business, San Francisco, California. Location of works, Butte Township, Sierra county, Cal.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 8th day of March, 1875, an assessment of one dollar (\$1) per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, northwest corner Pine and Sansome streets, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 15th day of April, 1875, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
LOUIS VESARIA, Secretary.
Office, Northwest corner Pine and Sansome streets, San Francisco, California.
Manhattan Marble Company of California.—Location of principal place of business, San Francisco, California. Location of works, Oakland, Alameda county, State of California.
Notice is hereby given, that at a meeting of the Directors, held on the 30th day of March, 1875, an assessment of five dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary of the company, at his office, Nos. 13 and 15 Fremont street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 30th day of April, 1875, shall be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 15th day of May, 1875, at 12 o'clock, m., to pay the delinquent assessment, together with costs of advertising and expenses of sale.
L. L. ALEXANDER, Secretary.
Office, Nos. 13 and 15 Fremont street, San Francisco, California.
Orleans Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Grass Valley Township, Nevada County, California.
Notice is hereby given, that at a meeting of the Board of Trustees of said corporation, held on the 15th day of March, 1875, an assessment of one dollar per share was levied upon the capital stock of said company, payable immediately, in gold coin of the United States of America, to the Secretary, at the office of the company, room 8, No. 315 California street, San Francisco, California.
Any stock upon which said assessment shall remain unpaid on Wednesday, the 21st day of April, 1875, will be advertised on that day as delinquent, and unless payment shall be made before, will be sold on Monday, the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
J. F. NESMITH, Secretary.
Office—Room 8, No. 315 California street, San Francisco, Cal.
Silver Sprout Mining Company.—Principal place of business, San Francisco, State of California. Location of works, Kearsarge Mining District, Inyo County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of February, 1875, an assessment of five cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, in San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 16th day of April, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 17th day of June, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
T. E. WINGARD, Secretary.
Office—Room 13, No. 318 California street, San Francisco, California.
Theresa Mill and Mining Company.—Principal place of business, San Francisco, State of California. Location of works, Coulterville District, Mariposa County, California.
Notice is hereby given that at a meeting of the Board of Directors, held on the 14th day of March, 1875, an assessment of twenty cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold and silver coin, to the Secretary, at the office of the company, Room 15, 408 California street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 14th day of April, 1875, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the 10th day of May, 1875, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
B. K. HENCOX, Secretary.
Office—Room 15, 408 California street, San Francisco, California.
Tuolumne Hydraulic Mining Company.—Location of principal place of business, City and County of San Francisco, State of California. Location of works, Tuolumne county, State of California.
NOTICE.—There are delinquent upon the following described stock, on account of assessment No. 4 levied on the 23d day of February, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

TO COPPER SMELTERS, BLUE-STONE and Sulphuric Acid Manufacturers,

For sale or to lease, the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations realized \$30,000 for Bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 200 tons 5 per cent. Supply inexhaustible. Tills perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction, \$. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. of pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Louis Chalmers, Silver Mountain, Alpine county, Cal.

TREADWELL & CO.'S

(IMPROVED)

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call particular attention to the graceful and simple mechanism of this Engine Boiler; the in form not only pleasing to the eye, but is also, that secures the greatest strength and rigidity with a given amount of material. The Boilers, which are of the upright tubular style, with internal stay rods, are from 10 to 100 pounds per inch. The heating surface and area of grate are in excess of the quantities usually allowed for the same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is therefore not liable to be injured by the heat from the boiler. The fly-wheel being at the base secures perfect steadiness under the high speed which is necessary for economy of fuel. All parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the Engine can be detached from the Boiler and run independently, if required. In many points of simplicity, safety and economy, it is far superior to any other portable engine. Small repair or machine shops, or for hoisting, wherever a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

PORTABLE
Engines
Sole Agents
TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine. For Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

A New Industry.

A collection of all the various articles of domestic and commercial use into which paper enters as the chief constituent, would form quite an extensive and interesting museum. With the expanding progress of invention it is difficult to forecast where the end will be to the application of this simple yet useful material. So extensive has become its application that the rag bag of the housewife, the gleanings of the cheffonier, and the waste of the cotton mill, long since failed to meet the wants of the paper manufacturer in the way of new material, and almost the entire fibrous material of the vegetable kingdom, not even omitting the growth of the forest, has been called upon to supply this ever increasing demand for paper "pulp."

The latest use to which paper has been applied is the manufacture of barrels of various sizes, from the size of a fruit can capacity up to the largest packages employed for packing flour, sugar, etc.

Were we not already familiar with the paper collar, paper bosom, and even the full length extension of shirt, paper handkerchiefs, pants and coat—the last made even water-proof—we might have regarded the idea of a paper barrel as preposterous. But nothing in the way of handiwork possibilities can now surprise the ordinarily intelligent Yankee; and so, when some months since we heard that to that curious collection of machinery employed in the wonder working mechanisms that may be daily witnessed at the Pacific Barrel Factory of Flint, Peabody & Co., on Brannan street, near Eighth, was to be added still another set of machinery for converting the straw of our wheat fields into convenient packages for conveying to market the grain itself, we suppressed any demonstration of curiosity, but resolved to "keep an eye out" and watch closely the development of that new Yankee notion. True to our purpose, we have from time to time made some excuse or another for just happening in, you know, at the works, until one day the past week we observed the workmen actually engaged in making paper barrels, and judging from the *modus operandi* and the quality of the article produced, we see no reason why that institution would not better serve the public and themselves by converting their supply of timber into kindling wood, and turning their entire force to converting the waste straw of our wheat fields into the neat looking and substantial paper barrels with which they are now prepared to supply all who may be in need of that kind of package.

What is a Paper Barrel?

Is a question that the reader will very naturally ask—how is it constructed? In answer we would say that this barrel is made of successive layers of ordinary straw paper board, cemented together, and subjected in the process to an enormous pressure, the result of which is a compact sheet of considerable thickness, and of far greater resistive force than the same thickness of the toughest wood that the forest can produce. The sheet thus formed has its two ends dove-tailed, as shown in Fig. 1 of the accompanying illustration, which are afterwards brought together and closed in the form of a cylinder, as shown in Fig. 2, backed by a cleat of the same material, and held firmly in place by double pointed tacks, which are driven through and clinched on the inner side. The heads of the barrels are turned from wood and flanged, as shown in section, and inserted in the cylinder, and so secured as to be much stronger and safer than in a common wooden barrel. The barrel may be subsequently strengthened by hoops, either of paper or iron, as may be desired, although the former seems all that is needed. The resisting power and durability of these barrels will be perfectly apparent to any person who will take the trouble to examine them. The following may be mentioned as

Some of the Advantages

They possess over the wooden barrel. Their form being that of a uniform cylinder there is a saving of fifteen per cent. in stowage. This

would be a large gain in stowing in a vessel, and also in cost of storage in warehouse.

They have successfully stood all trials as to liability to burst, having been tested with 4,000 pounds inside pressure without bursting.

The paper is made water proof, impervious to air or moisture, and hence is not liable to absorb the odors arising from other articles when stored together in a vessel, and being about air tight they are especially desirable as a protection against the insects and vermin which abound in warm climates and against

than boxes. They are also proof against dust, bugs or insects, as they are so tight that none can enter.

They can be unheaded without injury to barrel or head, and when empty will form a valuable and even ornamental article for many household purposes, such as for the storage of

Paper Barrel Complete.

Paper Barrel in Parts.

loss of flour or sugar by sifting out in handling.

They are more easily handled than the wooden barrel, as they roll at a true angle, while the wooden barrel, from its convex shape, is liable to roll in any direction. Nei-

soiled clothing, furs, linen, vegetables, etc. They are especially calculated as desirable packages for flour, sugar, rice, cheese, butter, meal, grain of all kinds, coffee, spices, dried and other fruits, etc.

Fig. 1. Main and auxiliary sluice-boxes. A, rock-pavement; B, large iron pipe; C, small pipe.

ther will the heads fall out as readily as those of wooden barrels.

They can be shipped each part complete, and set up as required, thus saving much

At some future time, when the machinery is in more full and complete operation, we propose to give a detailed description of the machinery by which they are constructed, and the

Fig. 2. Arrangement of undercurrent, (perspective distorted to show details.) A, first tap; B, second tap; C, platform of undercurrent; D, widened boxes; E, main sluice.

space and cost in transportation; and in this way any man can be his own cooper. Any boy can put them together. A smart boy can set up from one hundred to one hundred and fifty barrels per day. The hoops are only added for protection in rolling, so that if they become loose, or are even knocked off, the barrel is in no degree impaired.

The paper from which the barrel is made is manufactured from wheat straw, and it is evident that nothing can be cleaner or sweeter for the packing of flour than the straw on which it is grown. And the same advantage applies to sugar and many other articles.

These barrels are lighter and more easy to handle than any others of equal capacity, or

misfortune, soon after they started on the Potrero, to lose their entire stock and machinery by fire. But, nothing daunted, they immediately ordered new, more perfect and more extensive machinery, and rebuilt at their present location. They have been constantly adding new and improved machinery from time to time, thus keeping their establishment constantly abreast of the best appointed institutions of the kind in the country, and always ready to supply the public with the best character of work. It is in furtherance of this desire to be behindhand in nothing, that they have just added the new feature which forms the subject of this article. We may also add, in concluding, that much of the success of this enterprise has been due to the energy, urbanity and untiring devotion to his charge of the chief manager, Mr. James L. Crosset, who has been in charge of the works from their very first inception until the present time.

Hydraulic Mining in California.

No. 21.

Figure 1 represents the sluices running on a higher grade than 6 inches to 12 feet, to make the difference in grade which exists between the two sluice-boxes more prominent and perceptible. A represents the rock pavement in the main sluice-boxes flush with the grating. B is an iron pipe, large enough to supply streams of pure water in sufficient quantities, when necessary. C is a smaller pipe, leading a jet of water into the box below the grating. The small sluices, containing the strained gravel-wash, will gain, in a run of 250 feet, about 3 feet and 6 inches high over the main sluice-boxes, the former running on 4 inches and the latter on 6 inches grade to the 12 feet. At this point—250 feet from the first tap—another grating and small sluice-box is established as before. At the same point the platform of an under-current, 36 feet long and of any desirable width, running on a grade of 12 inches per 12 feet, or 1 inch per foot, can be constructed. This platform connects at its lower end with the second smaller sluice-box, and empties its contents into that box, which needs to be enlarged sufficiently to carry, in a shallow stream, all the gravel and water received. It is supposed that another jet of pure water has been tapped from pipe B, and applied as before mentioned. It will hardly be necessary to say that all these arrangements should be carried on far enough from the main sluices not to interfere with them except at those places where the tapping takes place.

In Fig. 2 A is the first tap, running 250 ft. and gaining 3 ft. 6 in. over grade of main sluices. B, Second tap from main sluices, 3 feet 6 inches lower than the first. C, Platform of under-current, on 1 inch per foot grade, and 36 feet long. D, Widened boxes, running on 4 inch per 12 feet grade. E, Main sluice.

We have here, then, in a distance of 250 feet, and without loss to the grade or elevated position of the main sluices, an under-current of 36 feet length and 1 inch per foot grade; and we can repeat the arrangement for every similar distance, and without losing control of the strained gravel, etc., which is carried onward independent of the mass of material in the main sluices.

The finer gravel, which is gradually extracted from the main sluices, must be collected into one box, increased in size as new tributaries empty into it. Considering that only very fine gravel, with an increased supply of water, is carried by these boxes, they may be made very wide, so as to permit the gravel and sand to spread and run in a thin stream.

To regulate the overflow, triangular checks, as represented in the platform C in the last sketch, may be used, one of the angles turned toward the stream.

If a drop is preferred, from time to time, instead of an under-current, or its platform, a very strong and tight box should be placed below, and a few feet lower than the actual drop.

To the bottom of this box a strong iron pipe, 1 or 2 inches in diameter, may be adjusted, being, at the same time, connected with the supply-pipe which furnishes the water along the line of sluices.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

Coal on the Pacific Coast.

At the 1st meeting of the California Academy of Sciences, Amos Bowman, formerly of the State Geological Survey, read the following paper on the "Coal Deposits of the Pacific Coast."

By permission of the Chief Engineer and Directors of the Central Pacific railroad company, I hope to be able to present to the Academy, shortly, for examination and criticism, one or more of a series of maps made by me, which accompanied a report to the Chief Engineer, Mr. Montague, of a reconnaissance, undertaken at his suggestion, and recently carried out by me in the employ of the railroad company.

The subject of this reconnaissance end of these maps is the coal deposits adjacent to the lines of communication of the railroad.

Where coal furnishes the sinews or motive power of all our traffic, and where the cost of getting it involves not only dollars and cents to the railroad company, but fares and freights, touching every pocket in the Pacific States, we are in a position to realize that the formations in which coal is found are worth knowing about, and that there can be a case where even fossils mean dollars and cents.

I had previously given attention to tertiary and principally surface geology as underlying the great industry of hydraulic placer mining, and to the "eriferous slate formation" of the mesozoic or middle age—in other words, secondary age, with its gold veins, as underlying the quartz mining industry of California, these two industries together yielding California, annually, over \$20,000,000 in gold.

The present study brings up the intermediate period, the *cretaceous*, and in its comprehensiveness it is, geologically, perhaps the most important. California pays out over \$6,000,000 every year for coal; the people of the United States are paying, at the low average of \$5 per ton, \$220,000,000 every year for coal; the civilized world is paying over a billion annually.

I wish to state, only very briefly now, a few of the leading facts that my reconnaissance developed:

1. The fact of the existence of two continents; a Cordilleran continent far to the west of the Appalachian continent, at the time when the peculiar condition of things arose in the West, which resulted in giving us our coal beds.

The outline of the Cordilleran continent of the period I was able to trace much more easily and with much more detail than I had anticipated was possible, with the data and the means at hand when I began. The rocks of the cretaceous period in the Pacific States are generally sandstones, merely locally metamorphosed, and the fossils found in them are so abundant that the contributions of geologists of the United States and other exploring parties have furnished sufficient data from which their general geographical distribution could be mapped with perfect reliability.

The Rocky mountains at our latitude were not a part of this Cordilleran continent, but formed one large island, extending from Denver to Santa Fe. The Overland railroad, where it crosses the summit of the Rocky mountains, follows what was the bottom of the sea, along a strait, extending through the Rocky mountains. At Salt Lake it strikes the ancient western continent of our coal period, and at Rocklin it leaves it again.

The sea extended not only from Omaha to the island of the Rocky mountains mentioned, but 270 miles west of the eries of the Rocky mountains, over what is now the Cordilleran plateau, as far as the Wasatch mountains, and down along the Colorado river into Arizona. On the west side it covered a large portion of Arizona, of Eastern Oregon, and of the interior of British Columbia east of the Cascade mountains.

The upper cretaceous and lower tertiary rocks embrace a series of formations which may be called the *Cordilleran coal measures*. Their fauna and flora are closely related to each other. Their lithological character and the geological conditions under which they were formed are identical, forming as they did a marginal deposit, extending clear around this Cordilleran continent of our coal period, and giving me a hundred thousand square miles of country more or less coal bearing.

That this statement may not appear exaggerated, I will add that the localities have been tabulated in the report referred to, by States and Territories, and located on the maps, and that the coals themselves, with accompanying fossils, were essentially collected or sent for by myself and Mr. Soupham, Assistant Engineer of the Central Pacific railroad. They are not packed away in boxes, but properly arranged and labeled, in paper trays, and placed on shelves, where they can be seen. There are about 300 specimens, representing the coals and coal measures, and they will speak for themselves.

In the table of localities where coal has been found are given the particulars of the size of veins or seams of coal as reliably as possible. Representative localities and representative coal deposits are thus placed before the eye, from which the conclusion is unavoidable and indisputable, that in respect to coal the Pacific States and Territories have not been left out in the cold.

Taking different basins, so situated around the margin of this Cordilleran continent as to be at tolerable regular distances from each other, it is found that the conditions for coal making were in general not unfavorable.

The test of this is the size of the veins in representative basins geographically distributed throughout. Considered either as to the extent of distribution, when compared with similar large areas in other parts of the world, or as to the thickness of particular veins in widely separated localities, where the conditions were most favorable, they do not seem to fall short of the rest of the world.

The quality of this coal of the Cordillera has been alleged to be sadly against us. Many will remember the time when we used to regret that we were so unfortunate as to have no timber suitable for ship building.

Our coal has been called "lignite" by experts because there was no other word in the dictionary for it. Several geologists have held on to the old fallacy, long since abandoned by leading geologists, that there was no "true coal" to be found in any other than one geological period. Not being "true coal," it could be nothing else than "lignite."

Neither the origin nor the chemical analysis nor the quality of the Cordilleran coals justify the old nomenclature. Hayden was the first to speak out on the subject. They are not lignites properly—a name presupposing that they are derived principally from ancient forests. In the vegetation that gave rise to these accumulations, there is a parallelism to that of the carboniferous coal deposits, a resemblance in method, though the plants were of different families.

To settle the question whether we must refrain from calling them "true coals," I set to work systematically. First, I collected and tabulated all the ultimate analysis that I could find. I found abundant material, representing all our principal coal basins, excepting that of San Pete, Utah. The comparison with wood, with peat, and with eastern and foreign coals, showed clearly that the title "true coals," as limited to any formation or period, is not scientific. Varying degrees of hydrogen, in association with oxygen, running down to anthracite, characterize our western coals, precisely like those of any other formation.

Next, as to the effective heat producing qualities, I collected the results of half a dozen series of elaborate experiments which have been made of our coals in comparison with others, and tabulated them along with the ultimate analyses. The showing is that, notwithstanding some of our coal is little better than peat, that some of it has a large percentage of ash, that most of it has a large percentage of water,—we have not only first-class coals, coking coals, gas coals, and anthracite, but nearly every other variety that can be desired, represented in the Cordilleran coal measures.

Wonderful Retention of Heat.

On the 30th of October last, about two o'clock in the afternoon, the large new air shaft of the Belcher mine, then completed to the 1000-foot level, took fire and was destroyed. The timber of the shaft all burned out and the rock fell in and blocked it up. After mature deliberation it was thought that it would be better and cheaper to sink a new shaft than to try to clear out the old one, so badly were its sides caved and so great was the quantity of rock that had fallen into it. The new shaft was sunk a short distance to the west of the old one. It has now reached a point near the 1000-foot level, where it will be continued down on an incline. The incline was started at the 1000-foot level, and carried up to meet the vertical portion of the shaft. The course of this incline carried it through the remains of the old vertical shaft, but as soon as it was tapped the men found that they could do nothing in it on account of the ashes, burnt earth and rocks that poured down into their incline. A tunnel was then run until it had reached a point a short distance west of the old shaft, when a vertical raise was made to the line of the proposed incline to be run up to meet the new shaft. The men then began to work down on the incline in order to reach the point from which they were driven in trying to come up. They have succeeded in getting into the bottom of the old shaft, where, much to their surprise, they find the rock still red hot. In trying to but in timbers they were set on fire, and in order to work at all it is found necessary to bring a line of hose into the place and play a stream of water upon the rocks wedged in the bottom of the old shaft. There is no timber on fire among the rocks. They seem to have been heated to a degree so intense at the time of the fire, that they have remained red hot ever since. When we find so small a mass of rocks as can be contained in the bottom of a shaft remaining hot for over five months, after having been heated to whiteness, should we be incredulous on being assured by scientists that the center of the earth, once a molten mass of rock, still remains in a molten state after untold ages? Nearly three years after the great fire in the Yellow Jacket mine, places were found in the lower levels where the rock was still red hot.—*Virginia Enterprise*.

THE BELCHER ore breasts are looking well and holding out beyond all expectations. The mine is yielding 500 tons of ore per day. The air shaft is down to the 1000-foot level, and is fast drawing off the hot air and cooling the lower levels of the mine.

THE new pumping machinery for the Utah mine is on the ground ready for erection as soon as the foundation for its reception is completed. This portion of the work is being pushed with all the energy possible.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening Apr. 5th, Vice-President Henry Edwards in the chair. There was quite a full attendance of members. The donations to the cabinet comprised several bird's nests, of San Joaquin county, donated by Charles D. Gibbs; collections of plants from Wasatch mountain; grasses, barks from the Sandwich Islands; oil nuts by Mr. Frink; plants, etc., from Japan, by Professor Davidson. The library received the usual monthly publications and periodicals.

Horatio Stone, of the Washington Art Association, delivered a lecture on the Unity of Arts. Mr. Stone made some complimentary allusions to the resources of California, and paid a graceful tribute to Mr. Lick in introducing the subject. The lecture was rather elaborate, but was listened to with attention.

Amos Bowman read a paper on Pacific Coast Coals, elsewhere referred to in this issue.

Professor Brewer exhibited a map showing the distribution of woodland in the United States. It was prepared by running over all the counties of the States east of the Mississippi and marking what was timber land and what was not. These maps were prepared at the time the last census was taken. For the Western States the information was based on estimates derived from persons familiar with certain localities, coast survey officers, engineers, etc. The map was shaded so as to show the extent and comparative thickness of woodlands.

In speaking of the map Prof. Brewer alluded to the theory of the connection of the existence of forests with rainfall. There are no data of any authority to prove that the destruction of forests lessens the rainfall. In the investigations of the Smithsonian Institute no evidence has been found, in any part of the United States, that the destruction of forests has reduced the rainfall. The fact appears to be, but has not been proved by instrumental methods. He said, however, that in some places where rain gauges were kept only a few miles apart, the difference in rainfall was very marked; in some places it appeared as if timber affected it, and in others not.

Dr. Gibbons thought there was evidence to prove that there was a connection between forests and rainfall. Speaking of California, he said that, in regions very limited in extent, the rainfall varies very much in a few miles. The rainfall in San Francisco and Sacramento is nearly the same. At San Rafael, about twelve miles to the north, they have from one-half to two-thirds more rain than in this city. On the western side of the bay, to the south, near Redwood City and Mountain View, the average quantity is certainly not more than two-thirds of what there is here. As we advance to the south the average is gradually, but rapidly, lessened, and vice versa on the north. To the north there are extensive tracts of timber, and to the south there is comparatively little. It is worthy of remark, however, that the rainfall in the southern part of the state has been exceptionally large this year.

The President called the attention of the Academy to the fact that, as the Academy was founded April 4th, 1853, it was now of age and entering its twenty-second year. He hoped it would continue to prosper as well as it had done.

Dr. Gibbons exhibited a branch of poplar on the end of which a piece of mistletoe had grown in a peculiar manner. It came out from the end of the branch exactly as if it had been grafted artificially.

IMPORTANT ENGINEERING WORK.—A great engineering work, the only one of the kind in France, is about to be executed at Lyons. It is that of an iron bridge to connect the plateau of Fourvières with that of the Croix-Rousse, which are two heights, like that of Montmartre, in Paris, at a distance of 300 metres from each other. This undertaking is estimated to cost about 2,800,000 francs, of which a subvention of 600,000 francs only is asked from the city. This aerial bridge will consist of three spans, the central one of 135 metres and the two others of seventy metres each, resting on open iron columns in a line with the houses on the quays. The platform of the bridge will be sixty-five metres above the road and nearly fifty metres above the houses. Each of the two central columns will have inside a lift, by which pedestrians will be raised in two minutes, at a charge of ten centimes, to the top, whence they may reach the higher parts of the city, where they may have business. The only similar works existing in Europe are the Britannia Tubular Bridge in England, constructed by Robert Stephenson, in 1847, and consisting of one span of 569 feet and two smaller ones; that over the Conway, by the same engineer, of a stretch of 400 feet and the bridge of Dirschau, in Prussia, which has six sections of 129 metres each.

THE South California claim lies east of the Belcher and Overman, and about one north of the Woodville. A working shaft of three compartments is being sunk to develop this lead, substantially timbered, and now down eighty feet.

THE tunnel in the West Point mine, Weshoe, has been discontinued, as it would not strike the ledge low enough. A working shaft has been commenced on the ledge itself.

POPULAR LECTURES.

Economy of the Vegetable Kingdom.

Tenth Lecture Delivered before the University of California College of Agriculture, on Monday, February 1st, by Prof. C. E. BESSEY.

The Heath, Sunflower, Madder and Parsley Family.

The family we take up to-day is the *Heath* family, *Ericaceae*, a group including about 1,200 species. They are found mostly in temperate climates and usually in localities which are quite moist. They are inclined to grow in bogs and marshes and are trees, herbs, or shrubs, most of them being shrubs. A few of them are herbaceous, a few are white and ghostly, as the parasitic Indian Pipe, of but a few inches in height, and others again are tall and tree-like. Taking the order as a whole, we find that it may be said to be composed of the *Heath* family proper, of certain little outline groups, and in these outline groups, we have certain plants. The *Heath* found so abundantly in England, Scotland, and very abundant on the Cape of Good Hope has small leaves which continue green all the year.

While the most of the plants of the order are familiar with are shrubby, *Menziesia* and *Madrona* are trees, much removed in their aspect; they are usually pnt, however, into what is called an outline group of the order. Throughout the greater part of the group, including the *Heath* proper, there runs a narcotic poisonous principle.

Two of them furnish valuable timber. First, is *menziesia*, *Arctostaphylos glauca*, a native of California and other portions of the Pacific coast, and here I have a little block of *manzanita*, which will give you a pretty good idea of its wood.

The *madrona* is called *Arbutus Menziesii*, being named after Menzie, who made a great many discoveries along this coast.

[Professor asks if they know how far *menziesia* extends north. One student says, I know they are as far north as Siskiyou county.

[Speaking of a specimen of *manzanita* or *madrona*.] I should say this was fully

Equal to Rosewood.

I made the observation that I supposed they would not grow large enough, but was told that upon the mountains they grow to be very large; large enough so that they can get good pieces for making furniture. It branches out so that it can be used for veneering or any such purposes as that I have seen it made use of in a manufacturing establishment. They seem to be to cut it up into thin pieces. There were pieces put upon the furniture so as to represent raised panels, and in this way they use it quite largely. The *madrona* is a very fine wood. I see it stated in the books to grow sometimes to the diameter of twelve inches. Now, looking the whole order over, I find that there is but one other species well known which is large enough to be used in the arts at all and that is an allied species of this *madrona* found in Southern Europe, which attains about the size of our tree. So that we are very fortunate in having this very pretty and valuable wood.

Several species furnish food for their berries. *Gaylussacia* furnishes, in one or two of its species, what are called properly huckleberries, or frequently in the books, whortleberries. In the market, huckleberries and blueberries are mixed up and you can scarcely tell them, one from the other.

The *Cranberry*, belonging to *Vaccinium macrocarpon*, is now grown very extensively in certain parts of the East. Growers make cranberry bogs in wet places. This cranberry has a trailing stem, not usually more than an inch in diameter, usually grown in moss found in marshes. It is quite productive, and with its fruit you are probably acquainted. The difficulty in growing them here would be, the dry season.

If you have here what are called *sphagnum* bogs—this bog moss found in such places, having, in a high degree, the property of absorbing moisture from the atmosphere—you may be sure that you can grow the cranberry. A very few cranberries have been grown on ordinary dry land, but so far the experiment has not been very satisfactory.

A good many of the nurserymen in the East are advertising the nland cranberry. It doesn't amount to very much, you could not keep enough moisture around the roots in a tale. You will find, perhaps, down here, a very soft mud and running up sometimes for two feet, will be these old moss stems. The moss is growing at the top and dying at the bottom. Now, these cranberries seem to root very little down below this, and they trail along all through this. You have to imitate that to a certain extent; either by a system of irrigating or in some manner you must keep

The Lower Part of this Stem Moist.

Wherever growers have had any lasting success it has been only by imitating the natural growth. But, as I said, some are trying to grow it upon nland. Massachusetts and Wisconsin are the great districts for cranberry culture, and all the eastern markets are supplied from this source, excepting the supply from the wild bogs

SCIENTIFIC PROGRESS.

The Mission of the House Fly.

The mission of the house fly and mosquito have long exercised the ingenuity of the most curious and the most scientific. The generally received opinion is that they form one of the ills of life that was imposed upon humanity as a penalty for the undue curiosity or presumption which led to the expulsion of our first parents from the garden of Eden.

One possible beneficial use of the mosquito, inferred, in part, from the fact that it is found almost exclusively in malarial districts, is that its mission is to inject homoeopathic doses of quinine into the system, either as a warning to humanity to absent itself from such localities, or as an antidote to the malarial poisons taken into the system by residence in such places. We gave the views of the originator of this idea in a recent issue of the Press—to the end that they might be taken for what they were worth.

And now comes a Mr. Emerson, an English chemist, with rather more show of wisdom and science than was manifested in the propounder of the quinine theory, and gives us his theory with regard to the mission of the fly, which we find expressed in the *Scientific American* as follows:

Did you ever watch a fly who has just alighted after soaring about the room for some little time? He goes through a series of operations which remind you of a cat licking herself after a meal, or of a bird plucking its feathers. First, the hind feet are rubbed together, then each hind leg is passed over a wing, and then the fore legs undergo a like treatment; and lastly, if you look sharp, you will see the insect carry his proboscis over his legs and about his body as far as he can reach. Now the rubbing together of legs and wings may be a smoothing operation; but for what purpose is this carefully going over the body with his proboscis, especially when that organ is not fitted for licking, but simply for grasping and sucking up food.

This query, which perhaps may have suggested itself to thousands, has recently for the first time been answered by a Mr. Emerson; and certainly in the light of the revelations of that gentleman's investigations, the fly assumes the position of an important friend instead of a pest to mankind. Mr. Emerson states that he began his self-appointed task of finding out whether the house fly really serves any appreciable purpose in the scheme of creation, excepting as an indifferent scavenger, by capturing a fine specimen and gluing his wings down to a microscope slide. On placing the slide under the instrument, to the investigator's disgust the fly appeared covered with lice, sending the offending insect to be promptly released and another substituted in his place. Fly No. 2 was no better off than fly No. 1, and the same might be predicated of flies 3, 4, 5 or of *n* flies, as the algebras have it. Mr. Emerson concluded that there was something which at once required looking into. Why were the flies lousy? Meanwhile fly No. 2, on the slide, seemed to take his position very coolly, and, extending his proboscis, began to weep it over his body, as if he had just lighted. A glance through the microscope, however, showed that the operation was not one of self-beautification, for wherever the lice were, the trunk went. The lice were disappearing into the trunk—the fly was eating them! Up to this time the investigator had treated his specimen as of the masculine gender; but now he changes his mind and concludes it to be a female, busily devouring not her own progeny. The flies then carry their young about them; and when the family is too numerous or the mother too hungry, the offspring are eaten.

While reasoning thus, Mr. Emerson picked up a scrap of white writing paper, from which a fly appeared to be busily eating something, and put it under the instrument. There were the progeny again on the paper, and busily rubbed off with a cloth. "This," he says, "set me thinking. I took the paper into my kitchen again and waved it around, taking care that no flies touched it, went back to the microscope and there found animalcules, the same as on flies. I had now arrived at something definite; they were not the progeny of the fly, but animalcules floating in the air; and he quick motions of the flies gathered them in their bodies, and the flies then went into some quiet corner to have their diutiny meal."

The investigator goes on to describe how he continued the experiment in a variety of localities, and how, in dirty and bad smelling quarters, he found the myriads of flies which existed there literally covered with animalcules, while other flies, captured in bedrooms, or well ventilated, clean apartments, were miserably small and entirely free from their prey. Wherever filth existed, evolving germs which might create disease, there were the flies, covering themselves with the minute organisms and busily devouring the same.

Mr. Emerson, while thus proving the utility of the fly, has added another and lower link to the curious and necessary chain of destruction which exists in animated nature. These infinitesimal animalcules form food for the flies, the flies for the spiders, the spiders for the birds, the birds for the quadrupeds, and so on up to the last of the series, serving the same

purpose to man. He certainly deserves credit for an interesting and novel investigation, and for an intelligent discernment which might even attack the more difficult task of teaching as the user—for nature makes nothing without some beneficial end—of the animalcules themselves.

A New Gigantic Fossil.

We recently alluded to the reported discovery of a fossil skeleton of a gigantic beast, apparently of the bovine family, hat different from anything hitherto met with, either living or dead. The remains were found in some marshy land on the north shore of Lake Erie, eighteen inches under ground; while over them stood an oak tree three feet in diameter. A correspondent of the *Scientific American*, on hearing that the skeleton was on exhibition at St. Catharines, Ontario, Canada, went to see it and reports to that paper substantially as follows:

There are not many of the bones to be seen, but there was enough to give an idea of what the beast must have been. The horn, which was the most conspicuous, I found to be eight feet nine inches in length and two feet one inch in circumference, slightly spiral, considerably curved and tapering almost to a point. There are three pieces of the jaw, one of which is two feet long and contains the two back molar teeth, and is one foot five inches from the joint to the first molar tooth. The largest of the teeth are seven inches long, and three and one-half broad, measured on the face. A joint of the back bone measured thirteen inches in breadth and twenty-one in height. A bone said to be the third rib, is four feet five inches in length, and the bone from the knee to the ankle is seven inches across the top.

The horn in its present state weighs one hundred and five pounds, and one of the teeth weighs five and one-half pounds. The bones are in a very good state of preservation, and also the horns; but the teeth (which are tubercular) are perfect, the enamel being as hard and intact as ever. There is more of the skeleton still under the surface, which will be taken out as soon as the frost is out of the ground.

A New Utilization of Refuse Materials.

A very important discovery has recently been made by MM. Croissant and Bretonniere, of Mulhouse, France, which consists in producing dyes of a large variety of brown hues from substances not merely refuse, but in themselves colorless. The pigments are obtained by the reaction of alkaline sulphides upon ordinary wood sawdust, humus, horn, feathers, linen, silk, cotton, and paper waste, gluten, blood, and a number of other materials. In certain cases, when treated with the sulphides or polysulphides, the sulphur directly combines with the organic body; in others sulphuretted hydrogen becomes substituted for the hydrogen atoms eliminated.

The same body gives different shades, according to the degree of temperature, the duration of the operation, and the proportion of sulphide employed. The longer the heating and the higher the degree, the nearer the dye approaches to black. Humus gives a fine bistre shade, which does not fade, and is unalterable by organic or mineral acids, caustic lyes, soap, oxalate of potassa, etc. With bran a color is produced which subsequently, with bichromate, yields a fine brownish yellow or resin color, which can be changed to gray by the addition of carbonate of soda. Sawdust, preferably of oak, chestnut, and other non-resinous woods, gives a soluble dye of a brownish black, which appears upon the fabric of a greenish hue. It is possessed of high coloring properties and is very permanent.

CYCLES OF GROWTH.—A writer in the *Prairie Farmer*, who has lived on the prairies of Illinois for twenty years, thinks that many plants, if not all, have a minimum and maximum year for producing flowers and that these years are at regular intervals of time. They increase gradually from minimum to maximum, and then decrease gradually to minimum, thus forming a cycle. These cycles, differ in different plants, from four to seventy years. He suggests that this may account for the different varieties of grain "running out," and wishes others to make observations in this direction.

BURNING UNDER PRESSURES.—According to recent investigations by M. Caillaet, the results of burning sulphide of carbon, alcohol, and carburetted hydrogen, under pressures reaching thirty-five atmospheres; are that the flame arguments considerably in brilliancy, while the combustibility of the substance burned is notably diminished.

REWARDS AND PUNISHMENTS.—An English scientist, by way of experiment, injected arsenic into the veins of some dogs, for which he was fined by an English magistrate for cruelty to animals. Shortly afterward the French Academy of Sciences awarded him a prize of \$500 for his scientific researches.

NEW USE FOR THE CAMERA.—Among recent curious inventions is the application of the camera obscura to a railroad car, imparting to the traveling and wondering beholder a moving diminutive picture of the country through which he is passing.

BORAX.—M. Schretz states that borax enables the spontaneous movements of all living vegetable tissues and kills microscopic animalcules. In this country the use of borax as a preservative of wood has been patented.

MECHANICAL PROGRESS.

Filth or Foul Water the Cause of Boiler Explosions.

The following interesting matter is collected from a recent report of A. T. Hay to the Secretary of the U. S. Treasury on the subject of steam boiler explosions. His remarks are quite novel, and well worthy a close consideration:

When we boil pure water the steam rises regularly in spheres from the bottom of the vessel to the surface of the water. Steam at a like temperature and pressure has at all times the same number of molecules in a like volume, and the true measure of its energy may be calculated with mathematical precision. Water assumes three natural or allotropic forms—liquid, solid and vapor; in all these forms its qualities inhere. What is true of a molecule of water, ice or steam, is true of the whole volume of either—these several forms being due entirely to a change of temperature. Water is the most stable compound in nature; neither pressure, cold, nor heat alone being able to reduce it to its original elements.

Many of our most terrific explosions take place under a reduction of pressure; in fact, I have known instances wherein, just before an explosion ensued, the steam gauge would recede from 50 lbs. to 20 lbs. pressure, and no amount of firing would bring up the pressure sufficient to perform the work satisfactorily. If there had been a scarcity of water there would have been a surplus of steam. When boilers fire easily and steam freely there is no danger of any fearful disaster. If boilers give way under such conditions, it is simply from rapture, the effects of over-pressure, and not explosions in any sense of the term.

There can be no violent explosion from steam made from clean water, free from organic matter. At least, after many years' close observation, coupled with direct investigation and research, I have failed to find an instance where pure simple steam made from clean water ever exploded within a range of from 15 lbs. up to 500 lbs. pressure to the square inch. But I do find that explosions in steam boilers reveal in filth and foul water. Take, for instance, the Mississippi and its tributaries, and it will be found that steamboat boiler explosions have been most frequent in the vicinity of large cities, and as we go down the river. The Lower Mississippi has been termed a graveyard, while in that portion of the river above St. Louis, including the Illinois, where the waters are comparatively pure and free from nitrogenous matter, explosions have been very rare, while the Ohio, from Cincinnati down, is noted for many steamboat disasters. The most destructive and terrific explosions have occurred in the spring of the year, when the waters were loaded with organic substances, earthy salts and oleaginous matters.

When we boil foul water we find it tumultuous, accompanied with a low, bumping sound, with fits and starts, so sudden and violent in some instances as to jump bodily out of or even burst an open vessel. This antagonism to the boiling of any compound solution is caused by the attraction of these foreign particles for each other (chemical action and reaction), while in the boiling of pure water there is no chemical action whatever. Great rivers, like those in the Ohio, Mississippi and Missouri valleys, are great natural sewers, and their waters at certain seasons of the year are loaded with organic remains in every stage of putrefaction, while city wells and those around factories frequently become great sink-holes and receptacles for matter. My researches show that such waters hold in solution and carry in suspension from six up to sixty-three grains per gallon of organic substances, to which may be added copious quantities of oleaginous matter in certain localities and the salts of ammonia—N, H₃. These substances find their way into steam boilers, where they rapidly undergo chemical change, distillation, concentration, and sometimes violent decomposition—that is, culminate in terrific explosion.

These organic skeletons, glycerine salts, albuminous substances and ammoniacal gases found in water, consist chiefly of carbon, hydrogen, oxygen and nitrogen, and it is among such nitrogenous combinations and types that we find some of the most remarkable explosive bodies. They are not only aeriform, but they are gases of the most subtle and potent character; gaseous substances, in which the different elementary atoms are all chemically combined in the same molecule, that are liable to sudden and violent decomposition whenever the opposing forces to which they owe their existence become deranged by heat or some external cause. Their affinities are very feeble; hence their frequent destruction at high temperatures. Merely a molecular disturbance of any kind may cause violence. Their combination being internal and instantaneous, they develop a force at least ten times greater and one hundred times quicker than that of steam pressure—sudden and violent enough to destroy open vessels. But in clean water we have the most stable substances known, under the three distinct forms named, either of which may be safely had out of the other by merely a change of temperature.

As I said before, heat alone will not decompose water, but electrically readily resolves it into its original elements, and chemical action

being the source of electricity, water in the midst of sizzle and treacherous company becomes demoralized and loses its virtue and stability, and goes off in a gaseous state in times of chemical reaction. This frequently occurs when boilers explode, as neither water nor steam are ejected from them, but an inflammable gas is evolved. Under such conditions the engineer, dead or alive, is convicted of murder for allowing the boilers to become dry, when, in reality, a moment before the explosion his boilers contained a full gauge of water.

Electric Lathe Chuck.

In order to obviate the inconvenience and loss of time involved in the ordinary mode of fixing upon a lathe chuck certain special kinds of work, such as thin steel disks or small circular saws, the chuck is converted into a temporary magnet, so that the thin steel articles, when simply placed on the face of the chuck, are held there by the attraction of the magnet; and, when finished, can be readily detached by merely breaking the electric contact and demagnetizing the chuck. The face plate of the magnetic chuck is composed of a central core of soft iron, surrounded by an iron tube, the two being kept apart by an intermediate brass ring; and the tube and core are each surrounded by a coil of insulated copper wire, the ends of which are connected to two brass contact rings that encircle the case containing the entire electro-magnet thus formed. These rings are grooved, and receive the ends of a pair of metal springs connected with the terminal wires of an electric battery, whereby the chuck is converted into an electro-magnet capable of holding firmly on its face the article to be turned or ground. For holding articles of larger diameter, it is found more convenient to use an ordinary face plate, simply divided into halves by a thin brass strip across the center; a horseshoe magnet, consisting of a bent bar of soft iron, with a coil of copper wire round each leg, is fixed behind the face plate, each half of which is thus converted into one of the poles of the magnet. The whole is enclosed in a cylindrical brass casing, and two brass contact rings fixed round this casing are insulated by a ring of ebonite, and are connected with the two terminal wires of the magnet coils. A similar arrangement is also adapted for holding work upon the bed of a planing or drilling machine, in which case the brass contact rings are dispensed with, and any desired number of pairs of the electro-magnetic face plates are combined so as to form an extended surface large enough to carry large pieces of work. For exciting the electro-magnet, any ordinary battery that will produce a continuous current of electricity can be used; but in machine shops, where power can be obtained, it is more convenient to employ a magneto-electric machine—such as Gramme's for instance—rather than a battery.

New Mode of Raising Water.

Mr. R. F. Mushet, of Cheltenham, England, has recently invented and patented a device, whereby water and other fluids can be raised from a greater depth than has hitherto been practicable by the use of an ordinary suction pump. To the lower end of the barrel of an ordinary suction pump is attached a section of feed pipe, the united lengths of which barrel and pipe must not together exceed the height to which in practice a suction pump will raise a column of water. The lower end of the suction pipe passes into a covered reservoir or chamber, and extends nearly to the bottom of the same. A second length of suction or feed pipe is inserted through the bottom of the reservoir or chamber, and passes upwards to within a short distance of the top thereof. A similar arrangement of pipes and reservoirs or chambers is continued until the source of water is reached. The reservoirs or chambers are respectively supplied with water by any convenient means, a stratum of air remaining at the top of each reservoir or chamber. The pump is set in action in the ordinary manner, and the water is raised from the source of supply and discharged from the outlet of the pump-barrel. A check valve or valves is or are placed in the suction pipes for the purpose of sustaining the column or columns of water, and thereby rendering the discharge from the pump more uniform than it otherwise would be.

A LOCOMOTIVE HILL CLIMBER.—A new locomotive for use on Ithaca hill, N. Y., has made its appearance. The incline has five tracks, of which the two outer are of the usual width, used in the ordinary manner. When the engine starts up the hill it rests upon a pair of rails just within the usual track and upon a set of double flanged small driving wheels which are upon the same axles with the big drivers—they being only about thirty inches in diameter; this inside track is raised about fifteen to eighteen inches above the outer one, and high enough so that the big drivers do not touch the track at all; the engine rests now upon the small drivers, and is independent of the outer ones; then in the center of the track is placed a wide cogged rail, which exactly meshes into the cog wheel, which is between these small drivers; directly under the center of the locomotive. Thus it will be seen that, by applying power to the big drivers, in the ordinary way, the power is applied to the cogged wheel, which does the climbing. The cogs are about three inches from tip to tip, and the wheel is eight inches wide.

MINING SHAREHOLDERS' DIRECTORY.

Mining Stocks.

The market during the week under review has been without any noteworthy general movement. The Comstocks have been ready, with slight and comparatively regular fluctuations. Toward the close of last week a downward tendency was observable, which was only maintained for a time, but at the opening of the present week met with the customary relapse. Consolidated Virginia has declared its annual little dividend of \$1,080,000 and is the only Washeo mine now distributing dividends. It is expected, however, that several other prominent mines will soon come to the front with regular monthly returns to stockholders. Ophir, California and some of the old Hill mines are spoken of as probable dividend-payers.

Assessments are now in order. Yellow Jacket, Chollar and Hale & Norcross call for each, and California for \$3.

Among the outside stocks Enreka Consolidated and Raymond & Ely have attracted much attention. A sudden leap upward of 20 p

Mining Stocks.

The market during the week under review has been without any noteworthy general movement. The Comstocks have been steady, with slight and comparatively regular vibrations. Toward the close of last week an upward tendency was observable, which was firmly maintained for a time, but at the opening of the present week met with the ordinary relapse. Consolidated Virginia has declared its usual little dividend of \$1,080,000 and is the only Washoe mine now distributing dividends. It is expected, however, that several other prominent mines will soon come to the front with regular monthly returns to stockholders. Ophir, California and some of the Gold Hill mines are spoken of as probable dividend-payers.

Assessments are now in order. Yellow Jacket, Chollar and Hale & Norcross call for \$5 each, and California for \$3.

Among the outside stocks Enreka Consolidated and Raymond & Ely have attracted most attention. A sudden leap upward of 20 per cent. in each of these startled the market early in the week. With Raymond & Ely the other Pioche stocks strengthened in sympathy. Enreka Consolidated has been developing the new strike with flattering prospects. Steady and larger dividends are promised for the future. The Idaho stocks are on the up grade and are stiffening daily.

THE LOCOMOTIVE.—For some time past series of valuable illustrated articles has been running in the *Railroad Gazette*, entitled "Catechism of the Locomotive." These articles have now been published in book form, and are for sale at Bancroft's, in this city. It comprises a most exhaustive treatise on locomotives, in such a form as to furnish a clear and easily understood description of the principles of construction, and operations of the locomotive of the present day, a subject which is not so closely or adequately treated in any similar work. It is clearly and plainly written, in a manner decidedly advantageous for those who have not acquired studious habits of thought. To such the question asked presents first a distinct image of the subject to be considered, so that the explanation or instruction which follows is much more apt to be understood than it would be if no such question had been asked. The idea was taken from the German work on locomotives by Georg Kosak, and the work is largely quoted from. The work is profusely illustrated with all conceivable sorts of diagrams, so as to explain each thing in detail as it occurs. It is very comprehensive and full, and contains in the appendix tables "of the properties of steam," of "hyperbolic logarithms," "of the properties of different kinds of fuel," "of the resistance of trains," etc. This book is useful, not only to locomotive engineers, but to all classes interested in steam engines; and to students and apprentices it is invaluable. The author is M. N. Fournier.

THE Amador quicksilver mine is yielding about 100 pounds of metal a day.

HEAVY FLOW.—At the Lady Washington mine, on the Comstock, the miners last week suddenly cut through or into what is supposed to be the east wall of the ledge, encountering a snob a heavy flow of water that the men had to get out of there in a hurry. The water rose in the shaft rapidly, and although it has been taken out at the rate of 150,000 gallons per day ever since, it had attained a height of nearly 100 feet in the shaft day before yesterday. Since then the huge bailing tanks have been gaining upon it and the water is gradually lowering in the shaft. Like similar bodies or pockets of water found in the ledge, it will doubtless become drained out in due time.

A FLOOD of water was recently tapped in the Globe Consolidated mine, by the south drift from the main west cross-cut on the 400-foot level. Pieces of quartz and ore brought out by the flood are of a highly encouraging character.

THE frame of the new building for the incline machinery of the Ophir mine is nearly completed, and laying the foundation for the hoisting engine will be pushed to completion as fast as the nature of the work will permit.

THE erection of the new incline machinery on the Savage mine is nearly completed, and the developments on the 2200-foot level are looked forward to with great interest.

THE Hale & Noroross mine extracted 292 tons of ore last week; there are 2,764 tons on the dumps.

SEVERAL prominent silver mines in Bingham, Utah, have developed rich copper veins thirty feet wide.

At the Pacific Rolling Mills about 150 tons of rails have just been finished, beside the usual amount of miscellaneous work. The mills have been partly shut down during the past week, for repairs, but everything will be in running order with a full force on Monday. They are very busy at present. A large amount of work is being done for the mines; and in fact this class of work alone has, of late, been sufficient to keep the mills busy.

At the California mine the new machinery is fast arriving on the ground and the excavations for the foundations of the engine and other machinery is being pushed to completion as fast as it is possible for it to be done.

A PROJECT is on foot to establish a large foundry in East Napa, to be conducted by a joint stock company. Its purpose will be to manufacture stoves, etc.

CARSON river, it is said, will not be able to furnish sufficient water this summer to run the mills on that stream to half their capacity.

THE Pacific Tannery of Stockton recently

No less than 34,255 immigrants have arrived in California overland since April 1, 1874.

THE Chollar mine sent to mill 279 tons of ore last week, assaying \$34.27 per ton.

THE Enfera mine at Grass Valley cleaned up 300 ounces gold amalgam last week.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

RICH DISCOVERY.—Amador Dispatch, April 10: We are reliably informed that another richartz mine has recently been discovered about a mile from the town of Sutter Creek, which, from present indications, is likely to prove as valuable, when fully developed, as the famous Amador mine. The new mine is owned by the Hamilton mining company, and a shaft has already been sunk to a depth of 25 ft, at which depth the vein is three ft wide, and is increasing in width and thickness as they go down. About 80 tons of the rock has been taken out and crushed, and it yielded an average of 12.50 per ton.

MINING ITEMS.—Amador Ledger, April 10: Mining still continues in the Kennedy, and proposals for sinking 100 or 150 ft deeper in the main shaft have been advertised. The ore in the Kennedy at the lowest depths reached, looks very flattering.

Col. Whitesides, M. E., was in our county a few days ago making an examination of the royal League mine near Drytown, and should a report be favorable, the mine will again be placed in working condition.

The Gover, also near Drytown, at last reports was producing high grade ore from a very extensive body. The future prospect of the mine is represented as being very flattering. Considerable activity prevails in gravel mining with satisfactory returns. The heavy gravel claims along the line of the canal are being opened on a permanent scale, and as far as hydraulic power has been applied, the claims are looking remarkably well. When these claims shall be thoroughly opened (many of them presenting gravel over 200 ft in depth), it is but reasonable to expect a large amount of gold therefrom. Altogether the mining outlook of the county is very encouraging.

ALABAMA.

CLEAN-UP.—Calaveras Chronicle April 11: A recent clean-up at the Veith hydraulic claim, Tunnel ridge, after a run of thirty days, resulted in \$4,000. A cave that occurred during a month delayed operations somewhat. Hydraulics have multiplied rapidly in this vicinity during the past few years; and yet, considering the opportunities that have not been improved, at character of mining is still in its infancy.

NEW COSTA.

NEW RETORTS.—Contra Costa Gazette, April 1: The quicksilver company at work near Dayton are progressing satisfactorily in running their tunnels, and in accumulating good ore for the furnaces, which they have not been operating for the past few weeks, as their retorting apparatus was not satisfactory. Their retorts were on a new and before untried plan, which was found defective on trial, and they have been replaced by others of well tested sort, and the furnaces will soon be again started in operation.

YO.

PANAMINT CONS. M. Co.—Panamint News, April 6: This is the new company recently incorporated, which is now engaged developing the following mines: Don Juan, Jesse May, New England, California and Humboldt. The Don Juan is situated in Woodpecker canon, where is a 20-ft shaft and a 50-ft tunnel in the mine. The ore averages about \$100 per ton as comes out of the mine. The Jesse May is a quartz canon, and consists of 12 parallel shafts of quartz, of from three to four feet in width, all rich in ore and only a few feet apart. They have 100 tons of \$150 ore on the dump. In tons of \$300 ore have been assayed and assayed. The other mines of the company are being worked.

TWILIGHT.—This mine is on the north side of Sunrise canon. On this ledge an open cut has been run for a distance of 20 ft, and some 15 ft from the cut a shaft has been sunk to a depth of 30 ft. At these points a ledge fully 15 ft in width is shown. The country rock is limestone, but it is entirely covered up by the debris from the main or porphyry mountain. About one hundred tons of ore have been taken out of that assay, on an average, \$200 per ton.

SUNRISE.—There is piled up on the dump of this mine not less than 500 tons, and there is a sight in the different openings made, not less than 1500 tons more—all free milling ore. It is more will be taken out until the mill is ready for crushing. From the hundreds of assays made from this ore, the average is \$150 per ton.

The Emma lies about 1200 ft south from the Twilight, and is probably on the same vein. Work is just being commenced, and there has been efficient done yet to determine the width of this ledge, but thus far it maintains the same characteristics as the Twilight and Sunrise—the whole vein matter is chloride of silver free-milling. The owners of this mine are Messrs. Everlet & Moore.

ERN.

THE NEW DISCOVERIES.—Southern Californian, April 5: Very interesting accounts come from the new discoveries at Kernville. The whole range of mountains, between Kern and Inyo counties, is believed by our keenest prospectors to be rich in mineral. The first discovery was made by A. F. Bunnell, of Kernville, by accident,

while out prospecting in the rough, almost inaccessible mountains northeast of town, hunting for an extension of the Bull Run ledge owned by Gilpin and others. The lead crops boldly out and can be traced at least a mile, Alfred F. Bunnell being the first locator. Seven claims of 1500 ft each have been located by John Dunn, Robert Butts, Daniel Thornton, J. S. Collins, James Bunnell and J. D. Batton. The lead runs parallel with the Big Blue, and about one mile west. An assay shows \$325 gold, with some silver and an entire absence of base metal. Work is now progressing. The mill of the Big Blue will be used for the present, crushing rock. The prospects are that Kernville will become one of the most important mining towns in the State.

NAPA.

CHROME IRON.—St. Helena Star, April 8: We learn from the party most interested, Mr. C. B. Sharpe, of Chiles valley, that he has sold out his chrome iron mine, situated near his ranch, in the aforesaid valley, to the firm of Tyson Brothers, of Baltimore. Their agent, Mr. Reiser, is still in this vicinity, and it was through him the sale was made. The ore will be brought by wagon to this point, and hence to San Francisco by rail. This is the first mine that has been sold in this neighborhood, and the ore from which, will come here. May it not be the last. We want mines to be sold and worked, and all the ore to come out this way. Every ton is productive of good to the business interests of our town.

COAL.—Calistoga Press: A coal mine was recently discovered about eight miles from Middletown, on Soda creek, by Messrs. Brown & Co., and looks and burns well. There is no danger of its giving out, as the ledge is about 40 ft wide. G. Ivanovich showed us a sample of the coal. It is pronounced by experts to be of very good quality.

THE CALISTOGA MINE.—It is well known here that when the mill stopped last fall the road leading from the mine to the mill was impassable, and that its condition was the sole cause of the stoppage of the mill. A thousand tons of high-grade rock was left at the dump, awaiting fair weather. After the mill hands were discharged, the managers of the mine considered it expedient to put a large force of men at work on the prospecting tunnels, and to that end have been to work on three important points. First, tunnel No. 4, on the extreme south line of the mine, and 2,000 ft from the discovery point. Second, tunnel No. 3, about a hundred yards west of the toll-gate, and tapping the ledge 690 ft under the cropping, and third, tunnel No. 2, on the ore yard, 385 ft under the cropping. This tunnel is on the ledge almost 260 ft, and the development on this level promises the most flattering results. The ledge has widened to about six ft, and the average assay has been \$130 per ton. About twenty tons per day are taken from the face and stopes immediately over the tunnel, and all of a character that shows the existence of a perfect fissure vein. Tunnel No. 4 is within about 40 ft of the ledge, and No. 3 will reach it in about 65 ft. The mill is now in full operation, and we may confidently look for the silver bricks again.

NEVADA.

CINCINNATI HILL.—Foothill Tidings, April 8: We took a stroll over beyond Gold Hill one day this week and found a really live movement on one of the oldest locations in Graes Valley district—the Cincinnati Hill claim. Several years ago these claims, comprising 2,600 feet on the ledge, were largely worked through innumerable shafts, down to where water interfered, and a goodly amount of gold taken out. No machinery was ever put upon it, we believe, and a drain tunnel run in from a long distance only took the water from a depth of about fifty feet. Recently a company of Graes Valley men, having secured the title from the former owners, have made an earnest start, under the superintendence of Mr. John Bray, toward opening up these claims and working them below the water level. When we were there a large double shaft, inclining about 60 degrees, was down fifteen or twenty feet, the boiler, engine and hoisting rig set, and by the look of things they would soon be nicely under way. They expect to reach the ledge at the point above which it has been worked out, in five or six weeks, when affairs thereabouts will begin to get exceedingly interesting.

NEW YORK HILL.—Everything in and about this mine seems to be in a most prosperous condition. Rich rock continues to come from the lowest depths and a partial clean up made this week turned out a \$6,000 bar apparently as easy as any of the older mines of the district.

CALIFORNIA CONSOLIDATED MINE.—Nevada Transcript, April 8: The California Consolidated mining company own the California and the G-11 Tunnel mines, which are located on the hidden of Deer creek, about half a mile from town. The California is on the south side of the creek, and the Gold Tunnel on the north side. Mr. J. L. Holand is the Superintendent, and has held the position since August last. The ledge in the 420-ft level in the California averages from one to two feet in width and is composed of heavy sulphate rock. The last cleaning was made a day or two since at about 300 tons of rock, and yielded 832 ounces of amalgam, which is worth eight dollars an ounce. There was about 100 tons of sulphate saved, which will yield a hundred dollars to the ton. Therefore, the crushing yielded about \$8,156, or over \$27 to the ton. The hoisting at both mines is done by steam power. The

mill at the Gold Tunnel is driven by water power, and the one at the California by steam power. There is a new incline being sunk at the Gold Tunnel preparatory to the erection and use of new machinery so as to allow more extensive and systematic work. They are employing only 30 men at the present time at both mines. There are ten stamps in each mill and they can be kept running steadily on rock from the mine. As before said, the future prospects of the mine are first-rate.

PLACER.

RISING SUN.—Placer Herald, April 10: The new shaft of the Rising Sun mine, which is situated near Colfax, is now down about 500 ft. The work of opening up the drifts is being prosecuted with vigor. The ledge varies in size from 2 to 3 ft. About 20 men are employed in the underground works of the mine. The new hoisting works are, it is said, a model of neatness, convenience and good workmanship.

TUOLUMNE.

CINNABAR.—Union Democrat, April 10: The recent discovery in the vicinity of Marsh's Flat has attracted considerable attention from parties below. Mr. Dodge has returned from San Francisco with others attracted by these reports. If there is a paying lode existing, every effort will be made to find it by experienced miners and capitalists who are interested. A claim was recorded this week in the name of W. C. Ralston, which is a good sign that nothing will be spared to develop its value properly.

MAKES & DARROW.—Tuolumne Independent, April 10: The company are gaining depth very fast on their new hoisting shaft; it is expected they will reach the main vein in a short time. They are already getting small stringers of quartz in the rock and carrying rich sulphurets, indicating vein matter (and consequently solid lode not far distant). They are also refitting their three stamp prospecting mill, preparatory to testing and classifying the different gold and silver bearing quartz already discovered upon this excellent mine. The Superintendent is indefatigable in pushing the work ahead. We wish them all success.

ENCOURAGING.—The owners of the "New Albany," situated east of this place, were up from San Francisco last week on a tour of inspection, and went home more than pleased with their property. They have given orders to have a two mile ditch dug to the mine for power for a mill, which, in all probability, will be erected before long. The mine is sufficiently developed to warrant this expenditure.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill News, April 8: The north drift from cross-cut No. 2 on the 1500-ft level connected yesterday morning with cross-cut No. 3, greatly adding to the circulation of air in that portion of the mine, and proving the continuous extent of the rich ore from the south line to cross-cut No. 3, a distance of over 220 ft. Taking into consideration the fact that the last 20 ft of the south cross cut run on the south line of the Ophir is in rich ore, there is not a doubt left but what cross-cuts Nos. 4 and 5 will both find the ore vein as rich when they reach it as it is in cross-cuts Nos. 1 and 2. There are only 120 ft unfinished of the large air gallery on this level being carried forward to connect with the Ophir for ventilating purposes.

CONE, VIRGINIA.—Daily yield, 500 tons of ore. The joint east cross-cut on the California line, on the 1300-ft level, is in 200 ft, and will have 60 or 70 ft yet to run to reach the ore vein. The joint east cross-cut on the California line, on the 1400-ft level, has connected with the north drift from the ore breast, greatly assisting the ventilation of that portion of the mine. No prospecting is being done on the 1550-ft level at the present. The shipments of bullion up to last evening, for the past month amounted to \$1,701,000 with bullion enough not yet melted to swell the yield to \$1,750,000.

BECKER.—The main incline is down 11 ft below the 1600-ft station, the bottom still in very hard blasting rock. There is a considerable seepage of water in the shaft that interferes somewhat with the progress of the work. The south winze on the 1400-ft level is down 134 ft, the bottom still in good milling ore. The middle winze on the same level is down 115 ft, the bottom in ore that will pay for milling. The face of the north drift from the east cross-cut on the 400-ft level is in a fine quality of quartz, but has developed no valuable body of ore as yet.

OPHIR.—There is little or no change in either the appearance or yield of the ore breasts on the 1465-ft level. Sinking the northeast winze below the 1465-ft level is making steady progress. The new hoisting works building for the incline machinery is completed, and good headway is being made with the heavy stone foundations for the engine.

ANDER.—Work on the lower levels is making steady progress, with a very favorable prospect of the development of a fine body of rich ore.

WOODVILLE.—Sinking the new shaft is progressing at the rate of two ft per day, the bottom still in good working ground. The north drift on the 300 ft level is again being driven ahead, following the hanging clay wall of the ledge, which is well defined and of the regular Constock formation. The ore at this point is 22 ft in width, and of a fine character.

STEELE'S NEVADA.—Sinking the new shaft is making fine headway, the rock in the bottom blasting out finely, and no water to interfere

with the work. The large water tank at the 600-ft station is rapidly approaching completion. Driving the northeast drift on the 700-ft level of the old shaft is making good headway, the face in ledge matter of a favorable character.

CROSSLAR-POTOSI.—The south drifts on both the 1150 and 1250-ft levels are still being driven vigorously ahead, the face of both in porphyry mixed with ledge material.

OVERMAN.—The men have been taken from the drifts at the bottom of the winze on the 1100-ft level and put to work to enlarge the pump stations in the shaft preparatory to putting in the new and powerful pumps.

GOLDEN FLEECE (PEAVINE).—During this week 50 ft was added to the south drift, all through good ledge matter. The shaft being raised from the incline to the surface for hoisting purposes will be completed in about 14 days, when the engine and pump will be put in their places. Present assays average \$140 per ton.

UTAH.—The flow of water from the north drift on the 400-ft level continues so strong that all work on that level has been suspended for the present, and the tanks are kept as busy as possible hoisting the water to the surface.

LEO.—The ledge matter in the face of the main tunnel is steadily improving in character. The northeast drift shows the ledge to be very large at that point, and the formation is of the most promising nature.

HALE & NOACROSS.—The north drift on the 2100-ft level has reached the Savage line, and will connect in a very short time with the Savage works, which will give a much needed ventilation on that level. Daily yield, 60 tons of ore from the old upper workings.

BEST AND BELCHER.—The south drift from the bottom of the winze on the 1700-ft level is still driven vigorously ahead, without change of interest to report, if we except the rapid headway that is being made since the introduction of a Burleigh drill—the drift having been advanced 21 ft during the week, where only 5 ft could be made in the same length of time by hand work.

GOULD & CURRY.—The shaft is enlarged to four compartments, and is now in fine working order down to the 1500-ft station. The water has risen in the shaft to a considerable distance above the 1700-ft level, so that all work on that level is stopped for the present.

CALLEDONIA.—Sinking the new shaft is making splendid progress, the rock in the bottom blasting out finely.

SAVAGE.—Enlarging the drift on the 2200-ft level is making fine headway. The work of putting in a large water tank and pump station at the 2200-ft level is being pushed with all the vigor possible.

JULIA.—The face of the south drift, on the 1000-ft level, is still in soft porphyry, mixed with quartz of a very encouraging character.

SENATOR.—The body of quartz cut into last week proved only a hunch, yet the face of the drift continues in fine looking vein matter.

LADY BAYAN.—Owing to the breakage of a spur wheel of the pumping machinery and a stoppage of the pumps, the lower level of the mine is completely flooded, the water having stopped all work below the 250-ft level.

JUSTICE.—Water increases as the main incline attains depth below the 800-ft level. The face of the main drift south at the 800-ft level, from the incline, is in hard porphyry, very wet.

CROWN POINT.—Daily yield 500 tons of ore. There is no change in any of the upper ore producing levels of the mine. Opening the 1700-ft station is nearly completed. Everything in and about the mine is working finely.

IMPERIAL-EMPIRE.—The face of the south drift on the 2000-ft level is still in clay and porphyry. The face of the east cross-cut from this drift is in porphyry.

BALTIMORE.—The shaft is being thoroughly repaired and placed in the best possible working condition.

PAUL SHEARDAN.—The reddish brown stringers of quartz so plentifully met with of late, and which give such good assay, increase in frequency as well as in size.

BUCKEYE.—The water has been drained at the 550-ft station, and a drift started east to determine the full width of the vein, as the entire station is in ledge matter.

BULLION.—The body of quartz in the south drift on the 800-ft level continues to enlarge as the work of development progresses.

YELLOW JACKET.—The 1740-ft level is being gradually cased off by the connection with the Imperial mine, so that much better progress can be made with the prospecting operations in the future.

NIAOABA.—The ledge continues to show improvement as the shaft gains greater depth. The ore is of a fine grade and gives great encouragement.

NORTH CONSOLIDATED VIRGINIA.—The new shaft is down over 100 feet, with the bottom in fine looking ledge matter, which gives good assays.

KOSUTH.—The ore in the face of the south drift on the line of the ledge on the 350-ft level is showing considerable improvement as the drift advances.

OCCIDENTAL.—Cross-cutting the ore vein to the westward has been commenced.

ORIGINAL GOLD HILL.—The uprise above the cross-cut from the main south drift is all the way in good ore. Retimbering the main drift in place is the principal thing being done at present.

NEVADA.—The east cross-cut at the lower level gives an excellent showing of low grade ore, but no pay ore as yet.

Continued from Page 250.

throughout the States where it abounds. Oregon is here the source of supply.

A few species of the order furnish essential oils or essences. The only one that we need notice, is what is called the wintergreen. Its oil or essence is derived from the little plant, *Gaultheria procumbens*, called wintergreen. It is usually a little plant three to four inches high, bearing bright, red berries. They gather the plant and distill the leaves, distilling over the volatile oil used in medicine, flavoring candies and flavoring drinks. It is said to be stimulating, and so is more or less valuable.

The great importance of the order lies in its furnishing a large number of very beautiful ornamental plants, and wherever you find an *Ericaceae* ornament, you may be very sure of having always something quite pretty. The forms are always quite pretty. Take up a flower and examine it; it has all the perfection of a symmetrical form, instead of having a looseness as though it had not been quite finished. Indeed, I should say that among these plants are the most perfect forms we have.

The next one is the genus *Erica*, found in the region of the Cape of Good Hope. There are 300 species; perhaps 250 of them have been grown. I noticed in Woodward's Gardens quite a number of them. One species of *Erica* is the heath I spoke of a while ago. Rhododendrons grow usually to six feet in height, with large showy flowers. Azaleas, which may be seen in almost any greenhouse, have large, spreading flowers of all colors. I would caution you again against making free use of these plants, only as you know what they are. In fact, it is known that honey made from some of these, the Rhododendron, for instance, is Poisonous.

It would be injudicious to have very many of them growing near where bees are kept. The plant that covers the heaths of Scotland belongs to this family and originally belonged to this genus, *Erica*. But you understand that whenever we get a genus which has a great many species, there is a great temptation for the botanist to divide it up. There are now about 400 species of the genus *Erica*, so the botanists are splitting it to pieces. I think the true heath has been taken out of that. The only true *Erica* we have in the United States grows in two or three restricted districts in Massachusetts.

The Composite or Sunflower Family.

Composite, containing fully 10,000 species. It is what is called a very "natural" order; that is, any one seeing the plants would class them together, even without a knowledge of botany.

They are found in all countries and in all climates, having perhaps as wide a distribution as any order. Now, in all this vast assemblage, it is remarkable that there are hardly any trees. A considerable number are shrubby; but the great majority are herbaceous and very many of them are only annuals. A bitter, astringent principle runs through a large part of the order, but this very rarely becomes poisonous. There are a very few poisonous plants, but as a general thing you may chew of them or eat of them with safety. Though including so many species, comparatively few are of economic value. Perhaps, taking the number of species, this is the most valueless order we have. Under the food plants we have what is called the Jerusalem Artichoke, *Helianthus tuberosus*, a very near relative of the common Sunflower. This produces tubers resembling the potato; having very nearly the same general properties, and they are used in some places, because they are very readily grown. It is a perfectly hardy plant throughout the whole United States, so that the people need not replant it. If a field is once planted with artichokes, all that is needed is to cultivate it. I think it would be well to.

Grow it Where Swine are Kept.

It would be very valuable grown in this way; when the hogs are feeding on corn, and need a change of food, the grower could turn them in and let them get these tubers. The culture of the potato, however, has mostly driven out the Jerusalem artichoke. By the way, "Jerusalem" does not mean it came from Jerusalem. It is an American—Brazilian—plant, and was taken to Spain. In Europe it was called *girasole*; as it passed over into the English language, the common people got hold of it and changed it to Jerusalem.

True Artichoke, *Cynara Scolymus*, is a native of Southern Europe. In this case, instead of eating any tubers, we eat small, undeveloped flower scales, grown somewhat here and brought into the market. Jerusalem artichoke looks like wild sunflower, has every appearance of it. In fact, it is found more or less running wild all over the eastern part of the United States.

Silfry, or, as it is sometimes termed, vegetable oyster, *Trago pogon porrifolium*, is a native of Europe, grown for its roots, which are about as thick as this chalk pencil, growing six, to eight or ten inches in length. They are cut in each fall, and are used somewhat as ingredients in soup. It is worth growing, I think, in any place.

Lettnice, *Lactuca sativa*, is probably a native of Central Asia. It has been grown so long that it is now grown in every place. Eddive, belonging to the East Indies, called botanically *Cichorium edule*, is also another plant quite considerably grown for salad. Chicory, *Cichorium intybus*, a native of Europe, is grown throughout almost all portions of the United States for its roots. These are powdered, dried, and mixed with coffee. It is supposed to give it a little better taste. I think, however, for most people, the testimony is it does

not improve it very much. Dandelion roots and wormwood are valuable medicines, used largely, and arnica, used as a tincture, is found very valuable in serious wounds. These three, dandelion, wormwood and arnica, are almost all of the ordinary herbs in good repute mentioned in the dispensatory, while chamomile, feverfew, elecampane, southern-wood, and many others are what might be called domestic remedies. In the dispensaries you will find that they are not admitted as first-class medicines.

On the plains and in the Rocky mountain region several species of *Artemisia* furnish a large portion of the fuel. This *Artemisia* sometimes grows up some three feet high or so, mostly smaller, and they call it sagebrush. It is not the sage, by any means, but it is very closely related to wormwood, having nearly the same properties.

There are other forms, all used more or less, however, for fuel. [A student asks "What particular variety of *Artemisia* is it that furnishes food for animals?" That certainly cannot be a true sage. Is it bitter? [Student, "It is bitter until the frost." It is probably just one of these common species, one of these white ones. One kind is very white occasionally; sometimes more or less green. It grows east as far as the Missouri river, and I suppose, westward as far as the Sierra Nevada.

Among the ornamental plants, and there are many of them, are chrysanthemums, dahlias, sunflowers, zinnias, marigolds, and a great many others. Now, this order is peculiarly adapted to improvement. You take any one of the wild composites, and it is a very easy matter to change its form so as to double it, so as to make a quite ornamental plant of it, so that the flower will be quite attractive. The effect of cultivation may be seen in these asters, daisies and chrysanthemums. Wild dock is one; cultivation will double it. Now, this doubling is only changing the little double flowers of the great composite whole into the

Fig. I.

Ox Eye Daisy, or Whiteweed.

long, ligulate, or strap-shaped ones. Examine the next dahlia you see; you will find that the only change is as stated. There is no change, really, in the structure. Instead of the little floweret having that general form, it is split down on one side, considerably elongated, and has taken on a form like that. It is simply a very slight change in the corolla that brings about the result.

The whole order seems to have a very great tendency to become weedy. There is hardly a plant in the whole order but that has a tendency to become weedy, if it has a chance; so that out of the 150 species which may probably be found in California, undoubtedly one hundred may be found as weeds.

The Worst Weeds are Imported.

Thistle, cocklebur, rag-weed, bitter-wood, ox-eye daisy, may weed, beggar-tick, and dandelion are the most important of the weedy growths belonging to this order. Ox-eye daisy, or white-weed, [Fig. I.] grows East. I don't know whether it is found here or not. It has white flowers about an inch and a half across. [A student thinks it has been seen here.] It has a thin stalk, and grows always in very little bunches. I suppose the seed falls on the ground near it, so the plant will multiply both by its underground stems and by its seeds. It sends out little underground stems, so that a small plant is very soon a big one, and is quite troublesome to deal with.

One plant in the order is very peculiar. Growing all through the prairie regions of Iowa and Illinois we find what is called the compass-plant. It is in general appearance like the sunflower. It sends up from the ground a number of great radial leaves, and after awhile it sends up its flower-stem. Now, these leaves have the property of standing in the meridian. Why it is, or how it is, there does not anybody know.

The general shape of the leaf is very greatly lobated, reminding you of an enormous calyx. Now, that leaf stands almost always in that direction, so that one edge of it is to the north and the other to the south. You go to any of these plants—I have done so hundreds and

hundreds of times—and you will find all the leaves, except some two or three, apparently twisted around, though growing on every side. They twist around to the meridian. This peculiarity of the plant is made use of by the inhabitants quite frequently to find their direction. If you stand north or south of the plant and look towards it, you will see only the edge of the leaves; while viewing it from the west or east side, you will see those great, broad leaves standing out. Several years ago Dr. Gray attempted to explain it. It was suggested that a careful examination would probably reveal the fact that there were nearly the same number of stomata to be found on each side. Examination was made—the stomata were about equal. But the difficulty is, while that might account for the leaf trying to deal justly with its two sides, it will not account for this fact, which is very well established; that there are a great many other plants closely allied, the leaves of which do not turn in this way. So that, after all, Dr. Gray's suggestion did not account for the whole thing. You can not tell by these leaves any more about which way is north and which south than you can with your compass, if both ends of the needle are shaped alike. Of course you cannot tell which is which. I have seen this, where for some reason the leaf apparently wished to twist around where it had twisted.

More than Once Around,

Or over 360 degrees.

It is quite common for them to twist 160 to 180 degrees. All that grow in a certain position must twist around that far, at any rate ninety degrees.

The next is the Madder family, *Rubiaceae*, herbs, shrubs and trees, numbering nearly 3,000 species, mostly confined to the hotter portions of the globe. There are no timber trees which are of special value. There are some of local value. The order deserves its importance from the fact that it furnishes

Coffee, Quinine, Ipecacuanha and Madder,

Four of the most important vegetable products. The coffee tree is called *Coffea Arabica*. It was called Arabica because supposed at that time to be a native of Arabia. It is now found native in Abyssinia. It is a much branched tree, growing to the height of twenty feet. The

Fig. II

Leaves, Flowers and Fruit of Coffee Tree.

flower has a fragrance a good deal like the orange and the tree yields red berries as big as an ordinary cherry. Each berry has inside of it two seeds, which are the coffee seeds. (See Fig. 2.) These seeds always lie with their sides or faces approximating.

Examine a grain of coffee; cut it down carefully and you will find a little embryo, a very minute one, indeed. It will be necessary, perhaps, to boil the kernel before you can do this conveniently. It is of comparatively recent use, some accounts placing its introduction into Arabia somewhere in the fifteenth century; so it was about the time tobacco, potatoes and Indian corn were brought into notice. About 1560 it was first brought to London, long after they had been chewing tobacco. It was quite a good while before it came into general use. Now it is cultivated in the West Indies and considerably in South America, also in the East Indies. All these differences in locality have brought about differences in the coffee; but it is that we get from Arabia which is the best, occasionally to be found in the markets under the name of Mocha coffee. So, if you want to get the finest, highest priced, best tasting, buy Mocha. Java stands next, produced in the East Indies, largely upon the island of Java and usually it is next in price also.

The Rio coffee comes from the West Indies, South America, and a little of it comes from the extreme southern part of Hindostan.

Down in that part of Asia they grow it, and it is found to be the same quality and same grade as the Rio, so it is classed with it. It is the greenest and poorest. Now, it is found that if the very poorest coffee is kept for a long time in close boxes or chests, it is improved. If ordinary Rio is

Kept Ten to Fifteen Years,

It is found that in that time it will be fully equal to the best Mocha. The difference seems to be partly due to climate and largely due to the way in which it is preserved or prepared; the two go together somewhat. The West Indies and South America are not favorable to the long ripening which it should undergo. In

Java the climate is such that it ripens more slowly, while in Arabia the ripening is slower still. This is something parallel exactly with the ripening of the grape. In both cases we find the same thing—long ripening favors a higher development.

The second important plant is the *Cinchona*. There are several of the trees growing in the mountainous regions of Peru, Bolivia and New Grenada, and generally throughout the western part of South America. They all belong to this genus *Cinchona*. Of species belonging to this genus are *C. officinalis*, *C. calisaya*, *C. micrantha* and others. From a number of these species are obtained all the Peruvian bark and Jeeuit's bark. From the Peruvian bark we get, by manufacture, the quinine, which is really, I think, a chemical; I think it is an anaphate of the alkaloid or alkaline principle. It is used very largely now all over the world. This *Cinchona* was first made known under the name of Peruvian bark about 1640. Some of the Jesuits happened to be traveling in South America and made the discovery that it was valuable for fevers. They introduced it into Europe, and there is now a great demand for it. For a time there was a great danger that it would become extinct, so the English Government took steps to make plantations of it. There are now fine plantations in the islands of the West Indies, also in the East Indies.

Ipecacuanha, a very strong and safe emetic, is derived from *Cephaelis Ipecacuanha*, a small plant growing in Brazil. The root of this is taken, powdered and manufactured. It is perhaps one of the most generally used of all the emetics that are in general practice.

Madder is derived from *Rubia tinctoria*, which is a perennial, herbaceous insectivore, a native of the Mediterranean region. It is grown for its roots. The roots bear tubers which resemble those of the dahlia, but not quite as large, by any means.

They have a remarkably great amount of coloring matter in them. The roots are powdered and the coloring matter extracted. It is cheap, quite durable and very largely used in the red colors of calico and other cheap fabrics. It is grown largely in the United States throughout Southern Ohio, Indiana, Illinois and the adjacent regions, considerably also in Kentucky. If not already introduced into this State, it can be added as one of the industries.

The Parsley family, *Umbelliferae*. It might be called the humble family, because of the humble-looking inflorescence. It is quite extensive, including fifteen to sixteen hundred species, mostly herbaceous, although in the south temperate zone a few shrubby ones are found, and in one or two cases tree-like forms are known.

The order is mostly found in the north temperate zone. There are three distinct principles or properties to be found in the order, sometimes in the same plant. First, an acid, poisonous principle which is usually very abundant in the stems and leaves, so that these parts of the plant are generally to be avoided; an aromatic, wholesome principle is found in the roots, or seeds as we call them. You will understand that it has a form of fruiting, doublets, usually known as seeds; they are really two fruits. The third principle is a milky, resinous one. This is found usually in the roots, although it is found occasionally in the stem and other parts of the plant. A few of the plants are somewhat important. First, the parsnip, *Pastinaca sativa*, a native of Europe. In this case we eat the roots. If the plants have been well grown, grown rapidly, have not been made poisonous by too much sunlight, too much heat, they are quite palatable. The Carrot, *Daucus carota*, also of Europe, is used for the same purpose.

Both of these, if allowed to run wild,

Deteriorate and Become Poisonous.

Cultivation takes out the poisonous principle, and one may grow very good parsnips which will have no poison in them.

Celery, *Apium graveolens*, is a native of Europe, very well known. In this case, as is very well known, we eat the stems. Take the green stems and they are poisonous, but when this poisonous matter has been driven out by keeping the stems away from the sunlight for some time, they are quite wholesome. They grow it first, allowing it to be a foot high, and then throw earth, sometimes straw, sometimes boards around it—usually boards—so that the stem is kept away from the light. Whenever perfectly white, they are wholesome. Whenever acid, and I find some such are in the market here, you should throw them away; don't eat them.

Parsley, termed *Apium petroselinum*, is a native of Southern Europe, and is grown as a pot-herb. Some mix it up with their food. Now, in connection with all these, parsley, parsnip, carrot and celery, you must remember you are

Dealing with Poisonous Plants.

Among the aromatic plants we find caraway, coriander, dill, cum n, anise, fennel, etc. Of course they are harmless.

We get a few gums, first *asafoetida*, from the Northern *asafoetida*, a tall plant, native of Southern and Western Asia, and is grown there.

The main north drift on the 1740-foot level of the Yellow Jacket mine has made a connection with the south drift from the Imperial on the same level, thus curing a fine circulation of good air, and greatly aiding the development of that portion of the mine.

A new working shaft is to be sunk in the South Europa mine, on the Cometock,

Useful Information.

Coloring Process for Gems.

There is a factory in Idar, Germany, where the coloring of stones for art purposes is said to be carried on to a greater extent and more perfectly than in any other part of the world, the process pursued in thus converting chalcodony and red and yellow carnelian into onyxes resulting in the production of admirable specimens, which are known and prized in all the markets of Europe and America. The peculiarity of this process consists in the fact that the ribbons or zones in the different varieties of chalcodony—which, in the kidney-shaped masses of that substance, lie superimposed—differ in their texture and compactness; but owing to their similarity of color in the natural state, they can only be distinguished from each other with difficulty. The stone is, however, capable of absorbing fluids in the direction of the strata; and as the strata possess this property in different degrees, it necessarily follows that a colored fluid be absorbed, and the quantity taken up by the pores of the stone is different for every stratum of zone, a number of tints will be produced corresponding to the number of zones, each being distinct and colored in proportion to the quantity of the fluid absorbed. In this way a specimen of stone naturally but slightly colored may be rendered equal to fine stratified chalcodony or onyx, and may be employed equally well in the engraving of cameos, or for any other purpose where the variety of color can be rendered available.

THE POTTERY TANK.—Among the many vegetable products of Brazil, the pottery tree of Para, is not the least worthy of note. This tree, the *Mokilea utilis* of botanists, attains a height of one hundred feet up to the lowest branches. The stem is very slender, seldom much exceeding one foot in diameter at the base. The wood is very hard, and contains a large amount of silica; not so much, however, as the bark, which is largely employed as a source of silica in the manufacture of pottery. In preparing the bark for the potter's use, it is first burned, and the residue is then pulverized and mixed with clay in varying proportions. With an equal quantity of the two ingredients, a superior quality of ware is produced. It is very durable, and will bear almost any amount of heat. The natives employ it for all manner of culinary purposes. When fresh the bark cuts like soft sandstone, and the presence of the silica may be readily ascertained by grinding a piece of the bark between the teeth. When dry it is generally brittle, though sometimes hard to break. After being burned, if of good quality, it cannot be broken up between the fingers, a pestle and mortar being required to crush it.—*Am. Artisan.*

COATING SEAMS IN WROUGHT IRON TANKS.—Some one asks the *Scientific American* if there is any preparation for coating the seams of large wrought iron tanks so as to prevent the leakage of alcohol? The tanks are for storing it; they are perfectly water tight, but the spirit, being of a much less specific gravity than water, oozes out. To this query that journal replies as follows: Try cotton cloth soaked in lime, and cold rivet with this between the plates. Let us know if this succeeds, and also the results of other experiments tried by you, and we may be better able to inform you of a mode of procedure.

INTERESTING AND IMPORTANT CALCULATION.—It is estimated that of the 12,000,000 women in America, at least 11,000,000 wear calico dresses. It is not an unreasonable supposition that the spirit of economy here, during the past year, induced them to forego one dress apiece, or an average of eleven yards each, making, in all, a loss to the trade of 121,000,000 yards. This is nearly the entire product of all the Massachusetts mills for a year. From the above it will be seen how easy, from a slight inducement or necessity for economy, an overburdened market may be produced in the article of cotton goods.

OXYGEN AND EGGS.—In dry oxygen gas eggs are not affected, unless punctured. Moist oxygen decomposes the eggs. In moist nitrogen eggs will keep three months. Hydrogen the same. Eggs, whether pierced or whole, are perfectly preserved in carbonic acid, dry or moist. Illuminating gas the same. In chlorine water 1 to 500 eggs kept eight months in a closed vessel. In a solution of dilute chloride of lime, eggs would not keep ten days. Lime water and sulphate of lime kept them a little longer. Carbolic acid solution 1 to 500 preserved them about six weeks.

USEFUL HINT.—A kind of tracing paper, which is transparent only temporarily, is made by dissolving castor oil in absolute alcohol and applying the liquid to the paper with a sponge. The alcohol speedily evaporates, leaving the paper dry. After the tracing is made, the paper is immersed in absolute alcohol which removes the oil, restoring the sheet to its original opacity.

WOODEN SKEWERS.—The only manufactory of wooden skewers in the world, it is supposed, is at Toledo, Ohio, whence millions of them are shipped to England. They are made by machinery from hickory blocks. Between eighty and ninety thousand are turned out every day.

BET CIDER.—M. Plouard, a lawyer of Andelys, France, has devised a new cider, said to be very cheap and of excellent flavor—the peculiarity of which is that a large proportion of sugar beets is mixed with the apples before pressing; 80 pounds of beets are mixed with 700 quarts of apples, or about 11 pounds to 100 quarts. The beets and apples are pressed together, then saturated with water, left quiet in a cellar for twenty-four hours, and pressed anew. This is repeated seven times. The inventor says he makes 100 quarts of cider for 80 cents, which seems rather questionable.

NEW USE FOR GAS-TAR.—A gentleman in Burlington, Vt., of an investigating turn of mind, a week or two ago determined to try it again with the rats which infested his house. He purchased a supply of coal tar at the gas works, and placed small quantities of it in the rat holes in his cellar, and elsewhere in their runways. The rats, bedabbling themselves, became disgusted with the manner of their entertainment, and speedily left the premises, and have not been seen or heard from since.—*Sci. American.*

SLEEPING CARS.—Sleeping cars have ceased to be a luxury and have become one of the necessities of modern travel. It is said that the Palace Car company own 800 cars, which are operated on 32,000 miles of road. The average cost of these cars is \$17,500. In Pennsylvania they run their cars on 22 lines of road, and 17 in Ohio. Their net profit in these two States is said to amount to 14½ per cent. on the capital employed, from which 5 per cent. must be deducted for wear and tear, leaving 9½ per cent. net profits.

NEW APPLICATIONS OF ELECTRO-METALLURGY.—A very ingenious application of electro-metallurgy has recently been brought before the notice of the Society of Arts. It consists in the application of a coat of silver, by means of electro-deposition, on natural leaves and flowers. By this means very delicate ornaments are produced, since the precise form and texture of the natural leaf is preserved under the thin silver film. The special process by which these results are attained is the invention of Mr. Deaton.

AMERICA BEFORE THE DAYS OF COLUMBUS.—The supposition that America was known to the northern nations of Europe many centuries before Columbus was born is now very generally credited. The evidences in favor of that supposition are constantly accumulating. So much interest is felt in the matter by European scientists that an "International Congress" is to convene at Nancy, France, on the 19th of July next, of persons interested in investigating this interesting and important subject.

COMBINATIONS OF COLORS.—As an illustration of the limitless number of combinations which the three primary colors are capable of, it may be interesting to know that in the Gobelin tapestry manufacture 28,000 distinct shades of yarn are employed, each one distinguishable by the practiced eye.

Good Health.

To Produce Perspiration.

EDITORS PRESS.—One of your subscribers takes an interest in recommending the following recipe for family use. She has used it for years, and has never known any but good and satisfactory results, and through her some M. D.'s have confirmed her testimony by continued use of some where a sweating effect was desired:

Take gum camphor, saffron, ipecac and Virginia snake root, each one ounce; opium, half-ounce (pulverized); add one quart good fourth proof brandy, digest or soak two weeks, then filter or strain.

Dose.—For adults a teaspoonful every one or two hours, in a little warm herb tea to produce sweating. Useful in fevers, inflammations, colds, and wherever free perspiration is desired. When used for children, the amount and frequency of the dose should be modified according to age and circumstances.

Rio Vista, March, 1875.

How to BREATHE.—Civilized man is the only being that breathes through the mouth, which at once shows that it is an unnatural and acquired habit. The wild Indian would as soon think of eating with the nose as of breathing thus. The habit is usually acquired in childhood, and is generally the result of breathing impure air. It is then that the fond mother should guard her offspring with watchful care against this vicious and deadly enemy of her child. Let her follow the example of the wild Indian mother, and give her child the pure air of heaven to breathe, and if perchance it opens its little mouth during sleep, let her gently press its little lips together, until the habit of keeping them closed becomes fixed for life.—*Science of Health.*

If a wound made by a rusty nail be held for twenty minutes over smoke from burning wool or woolen cloth, the pain will be relieved and the worst case of inflammation allayed. This is simple and worthy of a trial, in these very frequent cases, which often result so fatally.

What the Health Lift Does for Exhausted Nature.

This era is one of condensation—from condensed thought to condensed milk—and the question here was how to condense exercise. Rather is it a gradual, easy, complete waking up of every torpid molecule in brain, liver, blood and nail, the sending through and possessing the entire man with a new sense, and re-creating him there, so that he returns from his few minutes at the lift a new creation. It doesn't seem to take the place of exercise exactly, but rather to make all exercise tell. It is the complement of the exhilarant to it. Never shall I forget the sensations of my first lift and my introduction to parts of myself unknown or forgotten. It seemed to be forever to the end of me—as if life was going out from its center to an infinite circumference, as if the eye were gone beyond fingers' ends, and would soar into, fill all space. Then a glow all over the body that was as luscious and cheery as any that have been told of by the Turkish bath enthusiasts, and then—I am afraid it may betray me—an exhilaration purer and more subtle and enduring than that of the best champagne. That was a red letter day, and though I have never felt quite that first, full joy again, my experience has been a record of many joys; joys that come of soothing and strengthening to a fagged brain, and a weary body and a pestered soul. I take my lift before my late dinner, when the day's work is done. I carry to it whatever weariness the day has made—of body, of brain, of heart—and I go away another than the man I came. Head-ache, limb ache, heart-ache are gone, or toned down to easy bearing, and a new counteractant vigor set at work in all the pulses. It seems to get behind the heart, and bolster that first seat of power and action. It is the best of rest.—*Rev. John F. Ware.*

Interesting Facts.

The organ of vision is considered the most delicate organization of the human frame; yet many who were born blind have been enabled to see by surgical operations, and the following is an interesting fact concerning one of that class: A youth had become thirteen years of age, when his eyes were touched by a surgeon. He thought scarlet the most beautiful color; black was painful. He fancied every object touched him, and he could not distinguish by sight what he perfectly well knew by feeling; for instance, the cat and dog. When his second eye was touched, he remarked that the objects were not so large in appearance to this as the one opened at first. Pictures he considered only partly colored surfaces, and a miniature absolutely astonished him, seeming to him like putting a bushel into a pint.

Stanly, the organist, and many blind musicians, have been the best performers of their time; and a schoolmistress in England could discover that the boys were playing in a distant corner of the room, instead of studying, although a person using his eyes could not detect the slightest sound. Professor Sanderson, who was blind, could, in a few moments, tell you how many persons were in a mixed company, and of each sex. A blind French lady could dance in figure dances, sew and thread her own needle. A blind man in Derbyshire, England, has actually been a surveyor and planner of roads, his ear guiding him as to distance as accurately as the eye to others; and the late Justice Fielding, who was blind, on walking into a room for the first time, after speaking a few words, said: "This room is twenty-two feet long, eighteen wide and twelve high," all of which was revealed to him with accuracy through the medium of his ear. Verily, "we are fearfully and wonderfully made."

THE VIRTUES OF BUTTERMILK.—Mr. Rebber, in a paper presented to the French Academy, thus extols the virtues of buttermilk: Life exists only in combustion, but the combustion which occurs in our bodies, like that which takes place in our chimneys, leaves a detritus which is fatal to life. To remove this he would administer lactic acid with ordinary food. This acid is known to possess the power of removing or destroying the incrustations which form on the arteries, cartilages and valves of the heart. As buttermilk abounds in this acid, and is, moreover, an agreeable kind of food, its habitual use, it is urged, will free the system from these causes, which inevitably cause death between the seventy-fifth and hundredth year.

READY MEANS FOR THE PRODUCTION OF OZONE.—Ozone may be easily and abundantly generated in an apartment by means of an aqueous solution of permanganate of potash and oxalic acid. A very small quantity of these salts, placed in an open porcelain dish, is all that is necessary, the water being renewed occasionally as it evaporates. Metallic vessels should not be used. Ozone, as most of our readers are aware, is remarkably conducive to health.

DARK HOUSES.—A dark house is always an unhealthy house, always an ill-aired house, always a dirty house. Want of light stope growth, and promotes scrofula, rickets, etc., among the children. People lose their health in a dark house; and if they become ill they cannot get well in it.

Domestic Economy.

Cooking Cranberries.

Cranberry sauce is the great American dish, and the most popular one for general use, either for dinner or tea. As a relish with game, poultry and meats of all kinds, it is unequalled. To every pound of fruit add three-quarters of a pound of sugar and half a pint of water. Stew over a moderate but steady fire. Be careful to cover and not to stir the fruit, but occasionally shake the vessel, or remove to a gentler heat, if in danger of sticking or burning. If attention to these particulars be given, the berries will retain, to a considerable extent, their shape, which is desirable and adds greatly to their appearance on the table. Boil from five to seven minutes, when they should be removed from the fire, turned into a deep dish, and set aside to cool. If to keep, they can be put up at once in air-tight jars. Very soft berries should first be removed and those remaining thoroughly washed, after which they should be placed in scalding water for about two minutes and then taken out; this removes a portion of the acidity, and a little less sugar will be required.

White sugar (granulated is best) should be used, and not too much water; the proportions given of each, it is thought, will suit the majority of tastes, but when otherwise, the quantities can be made larger or smaller, though in using sugar too freely, the distinctive cranberry flavor will be partially lost; some may prefer one pound of sugar where the amount specified is three-quarters, but probably others will be better pleased with less, perhaps with half a pound—especially dinner sauce—which makes the preparation very palatable, and has the advantage of economy; but when desired to keep a long time without canning or sealing, a larger quantity should be used. On account of the acidity of the fruit it is preferable, though not positively necessary, to use porcelain-lined cooking utensils.

VALUE OF A MILK DIET.—If any one wishes to grow fleshy, a pint of milk before retiring at night will soon cover the scrawniest bones. Although now-a-days we see a great many fleshy females there are many lean and rank ones, who sigh for the fashionable measure of plumpness, and who would be vastly improved in health and in appearance could their figures be rounded with good solid flesh. Nothing is more coveted by thin women than a full figure, and nothing will so rouse the ire, and provoke the scandal of one of those "clipper builds," as the consciousness of plumpness in a rival. In cases of fever and summer complaint, milk is given with excellent result. The idea that milk is feverish has exploded, and it is the physician's great reliance in bringing through typhoid patients, or those in too low a state to be nourished by food. It is a mistake to scorn the milk picher. Take more milk and less meat. Look to your milk-man, have large-sized, well-filled milk pichers on the table each meal, and you will also have sound flesh and light doctor's bills.

USEFUL HINTS FROM ONE WHO KNOWS.—Beef can be preserved for farmers' use by cutting it up, frying slightly, packing in a crock and covering with warm tallow. Beef tallow should be used for this, and kept perfectly clean and tried out nicely.

We cook hams in the same way in the spring, but consider them best without frying. They should be tightly packed and care taken that the warm lard fills up all the vacant places left by the meat.

Some housekeepers think that tallow is not fit for cooking purposes; but I think when it is properly rendered it is as good for some things as lard. I prefer it for frying doughnuts, and one of my acquaintances, a good cook, says it is the only shortening fit for mince-pie crust.

A PAN DOWDY.—Did you ever hear of a pan dowdy? It is an old-fashioned New England dish and has the flavor or our grandmother's cookery. Make a rich crust; line a deep earthen pot with it; now slice some apples quite thin for the first layer, strew the apples with molasses and spice and a teaspoonful of milk; cover with a thin crust and repeat the process. Cover the top with crust and your pan dowdy is made. Bake in a slow oven. A brick oven is made use of in New England generally. When done turn it on a platter and serve hot.

AN EXCELLENT BREAD PUDDING.—Soak two pounds of pieces of dry stale bread or toast all night in plenty of water, with a plate laid on the top to keep them under the water. Next morning pour off and squeeze out all the superfluous water; then mash fine the pieces of bread, mix with half a pound of cleaned currants, a quarter of a pound of moist sugar, four ounces of sweet chopped fine, and two teaspoonfuls of fresh ground allspice; grease the inside of a baking dish with a bit of suet, put in the pudding and bake four hours.

YELLOW ON SILK GARMENTS.—Boil the articles for half an hour in Marseille soap, with the addition of wheat bran; then rinse, and dye to a buff in a bath of soap and annatto, lift, and pass through a sulphuric acid bath of ½% Beaume, in which they will acquire a beautiful yellow color.

Manufacture of Agricultural Implements.

The Kimball Manufacturing Company are
enlarging their sphere of enterprise by the addi-
tion of a branch establishment for the man-
ufacture of agricultural implements. For the
accommodation of this new industry a commodi-
ous building, 90x220 feet in its exterior dimen-
sions, has been erected on the corner of Berry
and Sixth streets.

It is proposed to manufacture every imple-
ment needed on a farm from a garden trowel
to a lumber wagon. Heretofore our farmers
have depended almost wholly on Eastern man-
ufacturers for their implements and as a result
a large sum has annually been sent away which
could as well be retained to circulate in our
own State.

The most approved machinery will be intro-
duced by the Kimball company and they intend
that their agricultural implement depart-
ment shall be fully equal in reputation to their
other manufacturing departments which is a
sufficient guarantee of its excellence. The
building is two stories in height. On the
ground floor is the engine, of eighty-horse
power, twelve forges, lathes and necessary ma-
chinery. The upper room is divided into a
drying room, a painting room, wood workers'
room and an office for the Superintendent, Mr.
E. Soule. Between seventy-five and one hun-
dred hands will be employed when the manu-
facture is in operation, which is expected to be
about May 1st. In time it is the intention of
the company to add a foundry for the cast-
ing of such light work as is needed in their
business.

This will form a valuable acquisition to the
constantly increasing manufacturing enterprises
of San Francisco. We feel that its success is
assured.

RUBBER PAINT.—The U. S. Hospital at the
Pravido, and the Governor's mansion at Sacra-
mento, are both being painted with the rub-
ber paint manufactured by the Pacific Rubber
Paint Co., No. 207 Sacramento street. This
paint is fast coming into more general use as
its merits become known, and the manufactur-
ers have all they can do to fill orders.

Giant Powder.

The jury in the inquest relative to the recent
explosion at Rincon Point went out to the
Giant Powder Works on Monday last to wit-
ness a series of experiments with the powder.
The Mayor, members of the Board of Super-
visors, and a number of other gentlemen were
present. The manufacturers desired to prove
to the jury and others that the powder would
not explode by contact with fire, but would
simply burn up, unless the proper agents were
used to explode it. Giant powder, it may be
stated, is a compound of nitro-glycerine and in-
fernal earth. The particles of the nitro-
glycerine are absorbed in the earth, as if by a
sponge, and when ignition takes place, either
by loose powder or powder cartridge, a con-
tinuous and very hot flame is the result, until
all is consumed, but never an explosion.

The experiments were carried on a few burn-
ed yards from the Superintendent's resi-
dence, in the sand hills on the other side of the
Golden Gate Park. Boxes of Nos. 1 and 2
powder were carried to the spot, as well as a few
boxes of cartridges and some percussion caps.
Out of a box of fifty pounds of No. 1 giant
powder Mr. Varney dug a half spadefull, and
set it off with a piece of punk. It simply
burned up. The box of powder from which
this was taken was then ignited with a fuse,
but no cap, and it burned up in a fierce, broad
mass of flame. A box of ordinary cartridges
was then burned in a similar manner, but the
combustion in this case was less rapid, as the
powder was packed together and burned slower.
One of the cartridges being cut in two, one
portion was burned loosely, and the other was
placed over a heavy beam of wood, with a per-
cussion cap inserted. At last came the shock
and a shower of dust. The four ounces of
dynamite shattered the beam into fine splinters.
A 50-pound box of cartridges was now
placed upon an upright pole triangle, and a
weight of 100 pounds was allowed to descend
upon it from a height of thirty or forty feet.
Except in smashing the box and bursting the
cartridge, it had no effect. This shows that
simple percussion will not ignite the powder.
A fire being lighted, two shovelfuls of loose
powder were thrown into the flames; and then
cartridges were thrown in, and they all burned
up. A 50-pound can of No. 2 powder was then
ignited. Its conflagration lasted a couple of
minutes. Then five pounds of No. 1 powder
were packed tightly into a box and placed
among the live embers. The powder simply
burned away.

A quantity of loose giant powder was then
taken in a box and set on fire. When half con-
sumed a bucket of water was thrown upon it
and the fire quenched. The remaining half of
the powder, now saturated with water, was then
exploded with a cap. This experiment aston-
ished all present, who had no idea such a thing
could be done.

Experiments were now made to demonstrate
the extraordinary strength of the powder. Into
a mortar with a bore for a 32-pound ball a
quarter of an ounce of ordinary black
blasting powder was inserted as a charge. It
sent the ball a distance of precisely nine feet.
The same quantity of No. 2 giant powder
hurled the ball in a graceful arch a distance of
443 feet; and a quarter ounce of No. 1 powder
sent the ball 45 or 50 feet farther. A quarter
ounce was also tried without a cap. Not
enough power was developed to send the ball
out of the mortar. Thirty grammes (almost
an ounce) of blasting powder was next applied
to discharging a 32-pound ball vertically. This
was done by placing the ball in a cavity in
the upper side of a solid iron surface. When
placed in this hollow the ball was not quite half
imbedded, and rested directly on the powder.
The ball did not rise at all. With the same
quantity of giant powder it shot straight up-
ward about 1,000 feet. Half a pound of pow-
der, looking like ordinary damp sawdust, was
poured loosely on an 8x8 stick of timber, with-
out being tamped or otherwise confined, and
when exploded with a cap, it cut the heavy tim-
ber clean in two without splintering it at all.

Those present were thoroughly convinced
that when caps are not stored beside the pow-
der, though it is inflammable and gives out a
strong heat, it is an explosive not at all danger-
ous to handle. They were also convinced that
if 150 pounds of powder had exploded at Rin-
con Point it would not have left a vestige of
Hathaway's warehouse, or even the Marine
hospital. The general opinion is that when the
powder in the box on the floor caught on fire
from the sparks from Clark's pipe, the blaze
set fire to the fuse which was affixed to the
cartridge on the table, and thereby ex-
ploded only the 15 pound cartridge, which
caused the damage.

Upon returning to the city, the jury, with-
out hearing further testimony, returned the
following verdict:

We find that these persons came to their death by the
explosion of a quantity of giant powder, which was be-
ing prepared in cartridges in an office occupied by J. N.
Risdon, contractor for the removal of Rincon Rock.
That the explosion was occasioned by the setting on fire
of a fifty-pound box of giant powder by a spark dropped
from a pipe carelessly held by J. Clark, foreman of
the work, and one of the sufferers, which flamed up and
exploded a box of detonating caps lying on a bench a

few feet from an eight-pound cartridge just filled by J.
Curry. We think that J. N. Risdon, contractor for re-
moving Rincon Rock, and the occupant of the office
where the explosion occurred, should be greatly cen-
sured for permitting the manufacture of cartridges in
such a neighborhood, adjacent to dwellings and busi-
ness buildings, and suffering detonating caps and giant
powder to be stored on the same premises. We under-
stand that the city ordinances do not prohibit the
storage of giant or Hercules powder within the city
limits; and we recommend that an ordinance be passed
by the Board of Supervisors forbidding the storage of
giant or Hercules powder or dynamite in quantities of
over fifty pounds within the city limits, or the storage
of detonating caps or black powder in the same pre-
mises with giant or Hercules powder or dynamite, and
the absolute prohibition of the transportation through
the streets of this city of nitro-glycerine. (Signed, John
Taylor, Foreman; R. G. Brush, Thos. V. Fawcett, H.
H. Bigelow, Geo. W. Wyer, Isaiah Dixon, C. A. Kellogg,
M. J. Luddington, G. Forest Walter.

A New Gas Machine.

In walking down Beale street one day this
week we came across a newly invented gas ma-
chine of small proportions but large capacity,
which, as it will be shortly introduced in this
city and is a California invention, we examined
carefully. It is called the Hydrostatic Gas
Machine, and is run by air, water and gasoline,
in a simple manner. The water is admitted in a
small spray into a large-mouthed pipe. Thence
it goes into a receiver, where the air forced in
by the water, and which is carried down with
it, is stored. From this tank it passes through
a pipe or pipe, under a perforated diaphragm,
and upward through it and a film of gasoline
floating over this diaphragm. This film of oil
is kept constantly by means of communication
with a reservoir connected by pipes with the
carburettor, and as the carburettor is supplied
with water from a side tank by means of a
siphon, the water in the carburettor, in trying
to retain the level of this tank, flows down one
of the pipes connecting with the gasoline re-
servoir, forcing up, by its specific gravity, an
equivalent quantity of gasoline into the car-
burettor, where it floats upon the water already
there.

The air, after passing down through the in-
let pipe, and upwards through the perforated
diaphragm and gasoline film, is naturally dis-
charged with the gas, and is passed off through
suitable outlets to the burners.

This is the operation of the machine, which
appears, however, much more simple than a
description. The machine itself appears like
a small galvanized iron box with a few
connecting pipes, and occupies a space
of about two feet square. The barrel or
can of gasoline may be buried in the ground in
the back yard if necessary, or placed anywhere
out of the way, as it needs no attention after
being filled. The capacity of the apparatus was
examined is about two hundred burners, and
the whole cost will be about \$5 or \$10. The
whole thing runs by natural laws. When the
gas is turned on the machine begins to make
gas, and when it is turned off the action of the
machine ceases immediately; accordingly there
remains on hand only about enough gas to
start with, perhaps a cubic foot. Turning on
the gas at the burner also turns on the water
to start the machine, and vice versa. There is
no large gasometer to maintain, nor any ex-
pensive apparatus. As far as we can see there
is no danger of any explosion, as the gasoline
barrel may be buried in the yard, and there is
only a thin film of the substance in the ma-
chine, and that floats upon more than two
hundred times its bulk of water. This also
may be kept in a cellar if thought necessary.
This may be really called a poor man's gas
machine. The owners propose putting them
in houses in this city for the cost of meters
already in; and they inform us that the gas
co. (including water bill) from 90 cents to
\$1.10 per thousand feet.

The capacity of the smallest sized machine is
two hundred burners, and it makes gas in pro-
portion to the amount used, only running
when required. The cheapness of this ap-
paratus is greatly in its favor, as also its sim-
plicity and economy in working. It will
answer as well in the country as in the city, as
only a slight fall of water is necessary. Alto-
gether, the machine appears to us a simple and
effective one, and the owners are sensible
enough to put it at a price low enough to allow
any one to purchase. The first machines are
now being built at 139 Beale street. The in-
ventor is John C. Henderson, and we understand
that A. Chabot, Henry Pierce and G. R. Cot-
trell are the other owners of the patent. As
soon as all the arrangements are made the
machines will be put upon the market, and
judging from the men interested it will not be
long before this is done. It is different in op-
eration from any apparatus for similar pur-
poses heretofore invented, and its simple op-
eration and cheapness commends it to favorable
notice.

HOPE IRON WORKS.—Mr. Hanscom's new
works on the Potrero will be in running order
in about a month. The buildings are nearly
completed, the cupola furnace and the en-
gines are being put in place. Most of the
lathes, drills, etc., have been procured in
Philadelphia, and will arrive shortly. The
works are to be very complete, and the ma-
chinery ordered is all first class.

The machinery for the War Eagle mine has
arrived, and the mine is sending 20 tons of ore
per day to the mill.

Hydraulic Engineering in the Sierras.

In December, 1873, we gave a description of
the Virginia and Gold Hill water works, show-
ing by diagrams and engravings the details of
this great undertaking. The pipe as it now
stands extends a pressure of 1,720 feet perpen-
dicular, or 750 pounds to the square inch—the
greatest in the world. The average diameter
of the pipe used is 11 1/2 inches, and the entire
weight was about 700 tons. Nearly one million
rivets were used to manufacture it, and some
thirty-five tons of lead were consumed in
making the joints. At the point of heaviest
pressure the pipe is No. 0 thick, and is hot
riveted with 5/8 rivets, there being a double row
on the straight and a single row on the round
beam. The entire length of pipe crossing
Washoe valley is 37,100 feet.

These works are to be doubled in capacity
and another pipe ten inches in diameter is to
be laid across the valley. Marlette lake, which
is at an elevation of about 1,500 feet above O
street, Virginia City, is within a mile of the
eastern shore of Lake Tahoe and 1,000 feet
above its level. The lake has an area of 200
acres and is 15 feet deep when full in
winter.

The present supply is obtained from Hobart
creek, and is conducted for a distance of twenty-
two miles to Virginia. The creek is fed by
melting snows, and the amount of water is de-
pendent upon the character of the season.
When the snow fall is heavy and the thaw
gradual the supply is ample, but when the
snow melts rapidly early in the spring, the
volume of water is much diminished before
the season is over. The new works will take
the water from Marlette lake and add it to the
supply from Hobart creek. A tunnel half a
mile long is being run through to the mountain
range between Hobart creek and Lake Tahoe.
This is being worked from both ends by air
compressors and Burleigh drills. If considered
necessary, a shaft twenty-five feet deep will be
sunk on the line of the tunnel, and work can
then be prosecuted on four faces of the tunnel
at the same time. Six miles of grade are also
necessary to reach Marlette lake.

The pipe is the main feature of the under-
taking. The water is carried in flumes to the
eastern end of the pipe. From the outlet on the
eastern end it runs through a flume eight miles
long to Virginia and Gold Hill, connecting with
the city pipe system. The inlet of the pipe
has a perpendicular elevation above the outlet
of 465 feet. The supply, with the present pipe,
can be increased to 2,350,000 gallons per day.
The new pipe, which is to cross the valley, is
ten inches in diameter, made of iron, lap
welded. This will give ten pipes across the
valley, of nearly equal capacity, and the supply
will be greatly increased. There has been a
scarcity of water for mining purposes, but with
this supply more mills will be erected at the
mines, thus doing away with the expense of
hauling ore to reduction works at a distance.
The immense consumption of water is caused
by the building of mills, new hoisting works,
increased power of old ones, etc. The details
of this work are interesting to hydraulic en-
gineers, as the methods of tightening leaky
joints, the automatic air valves, blow offs,
elbows, straps, etc., are of novel construction
to stand the immense pressure. The additions
to the work will cost some \$500,000. Consi-
derable of this increased supply of water will be
used in hydraulic works. The ground, accord-
ing to the Gold Hill News, with water at a
nominal figure would have paid well, but op-
erations have been suspended for the present
on account of the expense incurred in obtaining
water.

MR. GEORGE SPAULDING, who has had bui-
ness connections with this office for some years
past, departed for the East with his family this
week, on a three months' trip. Mr. Spaulding
came to this State about twelve years ago. He
was at one time assistant foreman on the old
San Francisco Journal, and then foreman in
the Daily Flag office. He was foreman on the
MINING AND SCIENTIFIC PRESS for about five
years. He then bought out Dewey & Co.'s
job printing office and went into business with
Harrison Barto, under the firm name of Spaulding
& Barto, which firm is still successfully
running. Mr. Spaulding has been one of the
Board of Directors of the Mechanics' Institute
for over four years, and one of the managers of
three of the industrial exhibitions given by
the Institute. The managers of the Institute
gave Mr. Spaulding a dinner on Tuesday
evening last, on which occasion speeches were
made and a general good time enjoyed. Mr.
Spaulding is one of those quiet, unassuming
men, who unconsciously make friends every-
where and who "wear" well. In all our inter-
course with him we have never heard him ac-
cused of any incivility or unfairness of any
kind, and the estimation in which he is held by
his friends would be flattering to any man. He
has fortunately prospered in pecuniary mat-
ters by honesty and upright dealing, and is
now rewarding himself for close attention
to business by taking a pleasant trip. He goes
back to his old home at Fitchburg, Mass., for
a few weeks, and we, as well as all his other
friends, part from him with regret, and wish
him a pleasant trip and speedy return.

Baker's Rotary Blower.

This blower, illustrations of which we here-
with give, is made entirely of iron. The cylin-
drical portion or case is bored out and faced on
the ends. The heads of the machine, or ends
upon which the bearings are bolted, are also
faced off true. The case is secured to the ends
by bolts, and, when in exact position, the ends
are doweled so that when the case is removed
it can be returned to its proper position with-
out much trouble or delay.

The base is cast in one piece and faced on its
upper side, and bolted firmly to the ends of
the machine. The drums are each one solid
iron casting, turned up true and balanced, thus
insuring closeness and at the same time steady-
ness when running. The two lower drums are

nor will the machine have to be taken apart for
internal repairs.

The large illustration affords an exterior view,
and Fig. 2 gives a sectional representation of
the interior. The external case is made of
light boiler iron, formed up very truly and in-
serted into the heads of the machine, said
heads being of cast iron, firmly secured to a
bedplate of similar material. They are also
bolted together longitudinally by outside iron
rods. Within the case, and concentric there-
with, is a cylinder, A (a single iron casting),
which is provided with two vanes, B and C.
The shaft of the cylinder, A, is rotated by the
driving pulley shown outside. The air enters
at D, from underneath, and is forced by the
vanes out through the outlet, E, in the direction
of the arrow. In order to prevent any
direct communication between inlet and outlet,
two slotted cylinders, F and G, are arranged
on separate shafts, the latter actuated by gear-
ing on the main shaft (partially concealed by

ment's consideration, anposing the auxiliary
cylinders to revolve in the direction of the
arrows drawn within them, will show that,
whatever the position of the vanes may be, one
or the other or both of these cylinders will pre-
vent communication between inlet and outlet;
while their slots will always be presented to
the vanes so that the latter may, at the proper
time, enter and so pursue the uninterrupted
course necessary to drive a steady blast.

The manufacturers enclose to us a report of
the Franklin Institute Committee on this
blower, giving a comparison between the Baker
and Root blowers, in which the former has the
advantage. The Committee examined the ma-
chines in detail and in announcing the report
say, "Your committee are therefore of the opin-
ion that the Baker machine has proved itself
the best in every respect and entitled to the
first premium and diploma." The report is a
very flattering one to the Baker Blower and as
it is on file in this office can be examined by

The Old Bell to be Mended.

It is quite generally known that the old bell,
at Independence Hall, Philadelphia, which
first rang out the joyful news of our nation's
birth, has long been silent by reason of a seri-
ous fracture which made its appearance while
being violently rung on a Fourth of July occa-
sion many years ago. Although its ringing,
joyous tone has not been heard for these many
years, by reason of this injury which has been
heretofore considered past remedy, it has been
carefully preserved and shown to visitors at
Independence Hall, as a precious relic; and in
the preparations for the coming centennial
jubilee, a prominent place had been arranged
for it, where, in mute but eloquent silence, it
would form one of the connecting links be-
tween the past and the present.

But a better fate and better purpose, it is

BAKER'S ROTARY PRESSURE BLOWER.

slotted their entire length, to allow the wing of
the central drum to pass; these openings or
slots are made considerably wider than is
needed for the passage of the wings; this is
done to insure perfect freedom in action, and
at the same time to remove the danger of the
wings coming in contact when entering or
leaving. As each drum only acts as abutments
alternately, the power required to drive them
is merely to overcome the friction of the jour-
nals. The wings of the central drum are faced
off and bolted on firmly; they are cast in the
 requisite form to insure the greatest strength
in proportion to their weight. The gearing,
which is made exceedingly strong, is only in-
ended to keep the drums in proper position.

The bearings and journals are made extra
large, to secure as large a bearing surface as
possible, and to give to the journals a great de-
gree of strength, so as to prevent them from
springing in the bearing, and to overcome
rapid wear. A shield is placed over the gears
to prevent accidents. There is only one pulley
to each machine, and as this is made with a
diameter large enough to give the belt a good
running speed, and with breadth amply in-
sufficient for the purpose, the necessity of furnishing
extra belts, pulleys, counter shafts, &c., is
avoided, and the expense saved. The
great trouble heretofore has been to build a rotary
pressure blower, of sufficient strength,
fewness of parts and ease of motion to stand
the work they generally receive; whereas in the
improved blower the working parts are made
exceedingly strong, and there is no point in
actual contact (although working very close)
in its internal movements; hence the tendency
to hammer itself apart is entirely removed.
As there is no material to shrink in dry weather,
or expand in wet, nor into or bolts innum-
erable to become loose, the internal working
parts of the blower will not require replacing,

fast as the central drum. As the cylinder, A,
therefore turns in the direction of the arrow,
Fig. 2, the vane, B, is almost in contact with
the upper part of the casing, and is compres-

those interested. Further information can
also be obtained by addressing T. Wilbraham
& Bros., 2,314 Frankford avenue, Philadelphia,
Pa., sole manufacturers of the American pat-

Fig. 2

the figure on the extreme right of the large en-
graving) so that said cylinders revolve twice a
mining the air before it, driving the blast out of
the pipe, E. This compressed air is prevented
from returning to the inlet by the cylinder, F,
which above is close against the cylinder, A,
and below meets the abutments formed on the
bottom. The vane, C, at the same time has
entered the slot of the cylinder, G. A mo-

ent, or Charles Ashbury, Birmingham, Eng-
land, in relation to the English, French and
Belgian patents.

Besides their own big sixty stamp mill, the
Consolidated Virginia mining company is run-
ning the Mariposa, Occidental, Bacon, Kelsey,
Trench, Hoosier State and Sacramento mills—
eight mills in all.

hoped, is in store for the old "Independence
Bell." Mr. D. L. Riggs, of Salem, Oregon,
who has devised a method for mending broken
bells so as to restore their tone to their original
pitch, has been corresponding with the cen-
tennial authorities at Philadelphia, with the
view of trying his skill in the restoration of this
precious relic. The result of this correspondence
has brought an invitation to Mr. Riggs
to visit Philadelphia with this object in view,
and he has already gone thither. It is to be
hoped that he will succeed in the effort, and
that after its long silence, that old bell will
again resume its duty of ringing in the advent
of the "Glorious Fourth," from the bellfry of
Independence Hall, and that the first note of
its new-found voice will be heard when the
rising star of July 4, 1876, ushers in the cen-
tennial return of our country's natal day.

INDUSTRIAL IRON WORKS.—The foundry
and machine shop recently erected by Mc-
Cormick, Lewis & Co., on Beale street, and
known as the Industrial Iron Works, are now
in the full tide of successful operation. The
first "run" was made on Saturday the 3d inst.
At their works may be seen in operation Ba-
ker's Rotary Pressure Blower, the only one in
use, we believe, on this Coast. The Baker
Blower is said to be a desirable improvement
on rotary pressure blowers in the great strength
and absence of friction internally. The Messrs.
McCormick, Lewis & Co. have all the facilities
which improved machinery can afford and are
determined to do first-class work in every re-
spect.

The largest hoisting cable on the Comstock
lode arrived at Virginia City on Sunday, con-
signed to the Savage mining company. It is
4,000 feet in length and weighs 25,190 pounds.
It will be used in the incline.
